1 INTRODUCTION

2 Multimedia Domain (MMD) specifications [3] enable an operator to
3 apply Quality of Service (QoS) policy controls to the Internet
4 Protocol (IP) Connectivity Access Network on session-based
5 applications, and to provision flow-based charging rules at the
6 Packet Data Serving Node (PDSN). These current specifications are
7 confined to the PDSN as the sole policy enforcement point
8 supported.

9 The scope of MMD policy needs to be expanded to include overall
10 coordination of network resource usage for Session Initiation
11 Protocol (SIP) [4] and non-SIP applications for all subscribers,
12 enhancements to policy contexts, and incorporation of additional
13 network elements in the policy architecture.

14 This document specifies the system requirements related to these
15 MMD Policy Enhancements, which are intended to guide the
16 associated technical specification development.

1 3 DEFINITIONS AND ABBREVIATIONS

2 The terms and abbreviations which are used within this
3 specification are defined as follows:

1xRTT	1x Radio Transmission Technology
AF	Application Function
AGW	Access Gateway
AN	Access Network
AP	Access Point
AT	Access Terminal
BREW	Binary Runtime Environment for Wireless
CDMA	Code Division Multiple Access
DSL	Data Subscriber Line
EVDO	Evolution Data Only (a.k.a HRPD)
FW	Fire Wall
HRPD	High Rate Packet Data
IMS	IP Multimedia Subsystem
IP	Internet Protocol
MMD	Multi-Media Domain
NAT	Network Address Translation
NSP	Network Service Provider
PCRF	Policy and Charging Rules Function
PDSN	Packet Data Service Node
QoS	Quality of Service
SIP	Session Initiation Protocol
SLA	Service-Level Agreement
SSOO	Single Sign-On/Off
TCP	Transmission Control Protocol
TV	Television
VoIP	Voice over IP
UDP	User Datagram Protocol
UE	User Equipment
WCDMA	Wide-band CDMA

4 The following definition is used in this specification:

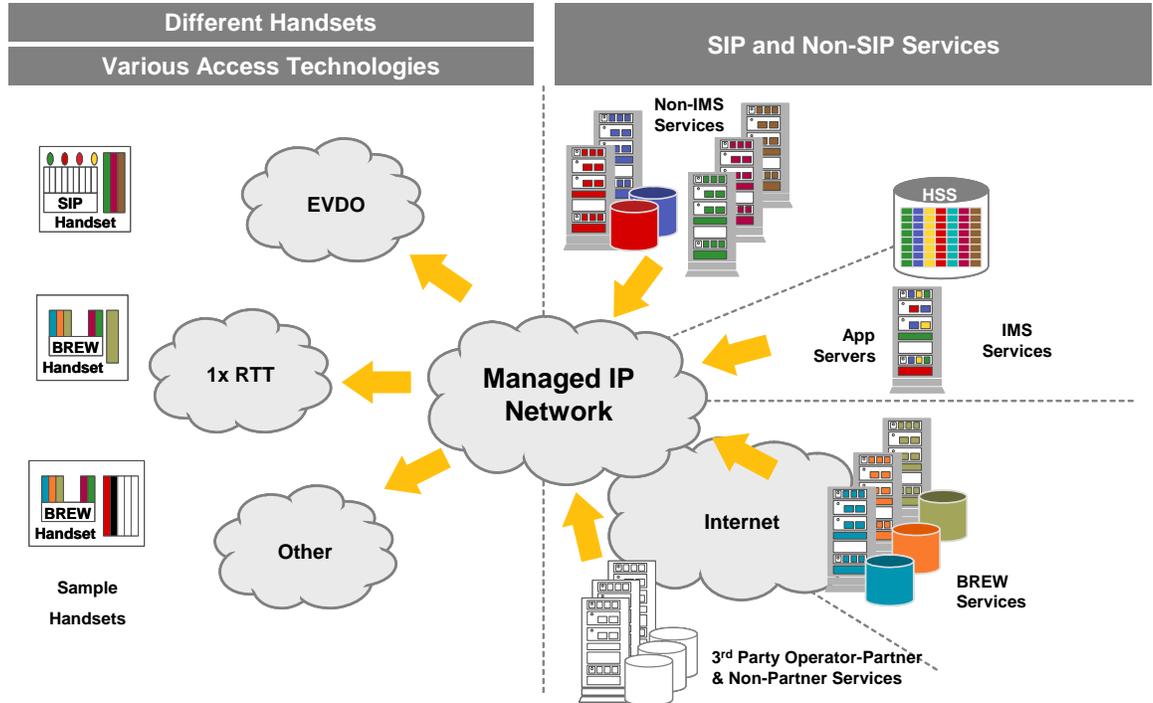

1 **IP flow:** Any identifiable (classifiable) set of IP packets from a
2 source to one or more receivers for which a common policy
3 treatment has been requested. For example, a stream of packets
4 having the same source address, destination address, protocol,
5 and Transmission Control Protocol/User Datagram Protocol
6 (TCP/UDP) ports is an IP flow.

1 4 GENERAL DESCRIPTION

2 Policy requirements entail QoS requirements in reference [2],
3 which specifies an end-to-end QoS model for cdma2000^{®1}
4 networks. While reference [2] advances a number of key QoS
5 requirements for wireless IP networks, there are other capabilities
6 which require policy treatment which are not discussed in that
7 document. These additional capabilities are an integral part of
8 evolution of MMD and are summarized in the following trends:

- 9 • **Support for both SIP and non-SIP applications.** It is
10 anticipated that MMD networks will be deployed by
11 operators who already have deployed non-IMS applications.
12 It is also anticipated that these operators are not likely to
13 replace these applications with IP Multimedia Subsystem [1]
14 (IMS)-based versions for some time, if at all. This coexistence
15 is exhibited in Figure 1 by showing how non-IMS-based SIP
16 services, IMS-based SIP services, non-SIP services (e.g.
17 Binary Runtime Environment for Wireless (BREW)) and 3rd
18 party services are expected to be provided as part of a
19 comprehensive services architecture. As it is likely that these
20 services will coexist for some time, policy requirements must
21 support the coexistence of both SIP and non-SIP
22 applications.

¹ cdma2000[®] is the trademark for the technical nomenclature for certain specifications and standards of the Organizational Partners (OPs) of 3GPP2. Geographically (and as of the date of publication), cdma2000[®] is a registered trademark of the Telecommunications Industry Association (TIA-USA) in the United States.

1
2 **Figure 1 A Comprehensive Services Architecture**

- 3
- 4 • **Support for multiple access technologies.** The QoS
- 5 requirements in reference [2] address cdma2000 access
- 6 networks. However, we anticipate that network operators will
- 7 incorporate access technologies other than cdma2000
- 8 (e.g., WiFi, cable, Digital Subscriber Line (DSL), Wide-band
- 9 CDMA (WCDMA), WiMAX, etc.) as they deploy network
- 10 capabilities enabling seamless mobility (see Figure 1). Policy
- 11 requirements must not preclude service operation over
- 12 disparate access technologies and should support multiple
- 13 access technologies.
- 14 • **Enhanced security.** The security policies which operators
- 15 deploy serve a crucial role in the operation of their networks.
- 16 Consequently, policy requirements must incorporate network
- 17 security.
- 18 • **Support for 3rd party applications.** As shown in Figure 1, it
- 19 is anticipated that operators, as they deploy MMD networks,
- 20 will take advantage of 3rd party applications and make these
- 21 applications available to their subscribers. The policies
- 22 governing the access to these applications also need to be
- 23 addressed in any set of policy requirements.
- 24 • **Support for ATs with multiple access technology**
- capabilities. The requirements should also consider the

1 Access Terminal's (AT) capabilities within a given access
2 technology and network.

- 3 • **Support for Network Address Translation traversal.**
4 Various standards bodies are developing network-controlled,
5 policy-driven architectures for Network Address Translation
6 (NAT) traversal; other standards organizations have client-
7 controlled architectures for NAT traversal. The policy
8 requirements of this document should target an appropriate
9 balance between these approaches.

10 The current MMD policy specifications primarily address policy
11 control over IP bearer resources and per-flow accounting.
12 Supporting the evolved MMD networks envisioned for the future
13 necessitates enhancing the current specifications to incorporate the
14 following items:

- 15 • **Expansion of policy contexts.** The current specifications
16 only discuss QoS and accounting. There is a need to expand
17 this list to include these other policy contexts:
 - 18 ○ **Mobility and Roaming Policy.** As part of
19 supporting multiple access technologies, a network
20 operator should also have the capability of
21 controlling whether or not a roaming operation is
22 permitted and whether or not a handoff operation is
23 permitted.
 - 24 ○ **Access.** As part of providing enhanced
25 authorization in an environment comprised of
26 heterogeneous access technologies, a network
27 operator should have the capability of controlling
28 access into its network based on an AT's security
29 status or account status, e.g., quarantining access
30 to a site which allows the subscriber to download
31 required security patches, refresh their pre-paid
32 balance or pay a delinquent account.
 - 33 ○ **Network Selection.** With the availability of
34 multiple access technologies, the network operator
35 should have the capability of defining policies used
36 by the AT for prioritizing network access and
37 selecting which Access Network (AN) it uses for
38 applications.
 - 39 ○ **Packet Flow Optimization.** A network should have
40 the capability of searching IP flows, within privacy
41 limits, in order to verify that the application
42 negotiated during session establishment is the

1 application actually operating. Additionally, for
2 selected applications incapable of requesting
3 enhanced QoS, the network should be able, by
4 monitoring IP flows, to detect such applications and
5 automatically employ network resources to provide
6 the appropriate QoS.

- 7 ○ **Traffic Engineering.** The services architecture
8 exhibited in Figure 1 demonstrates the need to
9 organize and allocate network resources in the
10 most efficient manner in order to meet customer
11 service commitments in the most cost effective
12 manner. A network operator should have the
13 capability of defining policies for admission control
14 and congestion management (e.g. identifying what
15 resources are allocated to an application, if and
16 how these resources can be modified by an
17 application, how the resources are modified during
18 network congestions, etc.).
- 19 ○ **Resource Selection.** When a user is in a visited
20 network, routing traffic related to low latency
21 applications back to the home network may result
22 in undesirable latencies and/or network
23 inefficiencies. A network operator should have the
24 capability of defining policies which result in route
25 optimization.
- 26 ○ **Authentication.** After a user agent provides
27 authentication credentials within an operator-
28 hosted session, subsequent re-entry of the same
29 credentials associated with subsequent session
30 hosted by the same operator should not be
31 required. Similarly, when a user terminates a
32 connection to an operator hosted session manager,
33 then all sessions which were previously
34 authenticated under that session manager should
35 be terminated. The collection of these capabilities
36 are commonly called Single Sign-On/Off (SSOO). A
37 network operator should have the capability of
38 defining policies for authentication credential
39 management, credential sharing, and related
40 protocol optimizations to support SSOO.
- 41 ○ **Content Screening.** Any content delivered by SIP
42 and non-SIP services may be subject to a set of
43 rules based on the subscriber/application profile
44 and content characteristics (e.g., age-based rating).

1 This alleviates each content source from
 2 implementing an independent content screening
 3 function.

- 4 ○ **Parental/Enterprise Control.** One subscriber has
 5 the ability to modify policy that applies another
 6 subordinate subscriber or set of subscribers. This
 7 allows a parent/employer to manage the rights of
 8 children/employees including charging limits and
 9 content screening.
- 10 ○ **User Personalities.** A subscriber has multiple sets
 11 of policy and the network selects a particular set in
 12 real time based on various conditions such as
 13 dialed digits (called party), incoming number (caller
 14 party), time of day, etc.
- 15 ● **Expansion of network elements.** The current specifications
 16 define policy control interactions among a limited set of
 17 network elements. Incorporating the additional functionality
 18 discussed in this section necessitates expanding the list of
 19 network elements impacted by the policy specifications. For
 20 example, when supporting Mobile IP [5][6], the home agent
 21 may need to be aware of the mobility policy since it is
 22 involved in mobility events between different access
 23 technologies. Since different network elements may be
 24 employed for different access technologies, the home agent
 25 may become a key location for managing a network
 26 operator's mobility policies. Additionally, as MMD networks
 27 grow, allowing additional network elements to participate in
 28 policy enforcement provides a more scaleable solution.

29 **4.1 Architecture Considerations**

30 The following goals should be considered when developing the
 31 policy specifications:

- 32 ● The policy architecture should not adversely affect
 33 performance (e.g., increase post-dial delay, prolong break
 34 time during hard handoff, etc.)
- 35 ● The policy architecture should allow localization of policy
 36 decisions to minimize messaging between network entities
 37 for some operations. For example, the RAN may cache policy
 38 information and make local policy decisions for handoff
 39 events.
- 40 ● The policy architecture should not inhibit system capacity
 41 from scaling both up and down, in terms of active
 42 subscribers & active sessions supported.

- 1 • The policy architecture should operationally scale (e.g., per-
2 subscriber provisioning of policy data should be minimized).
- 3 • The policy architecture should provide for consistency &
4 integrity of policy data.
- 5 • Policy-controlled packet-flow optimization should be
6 possible, especially for latency-sensitive traffic, so as to
7 minimize impact to traffic throughput in the packet data
8 subsystem.

9 Any successfully deployed policy must accommodate multiple
10 representations. As a policy reflects a system management
11 objective, it must be represented in a form understood by a
12 network operator. Since this same policy is implemented on one or
13 more network elements, it must also be represented in a tangible
14 form suitable for the network element. This implies that a
15 translation must exist between a system management objective and
16 its realization in the network. An example of such a translation is
17 between a Service-Level Agreement (SLA), and its objectives and
18 metrics (Service-Level Objectives, or SLOs) which specify services
19 that the network will provide for a given client. The SLA is usually
20 written in high-level system management terminology and must be
21 translated into lower-level specifications suitable for the applicable
22 network elements.

23 The main control elements for policy implementation is Policy and
24 Charging Rules Function (PCRF), which governs at the top-level
25 various aspects of policy. The policy rules are disseminated to
26 various other control elements in the network, including Access
27 Gateways (AGW), and Access Points (AP) (e.g. to implement policy
28 rules associated with medium access control and scheduling on
29 the radio interface). Though most aspects of policy are expected to
30 be implemented in the fixed network elements, some controls may
31 be conveyed to the AT from the network, as demonstrated in the
32 following example:

33 A roaming AT can contain two IP addresses, one assigned by the
34 home network, the other by the visited network. The policy
35 disseminated to the AT could be:

- 36 • MUST use the home network assigned address for SIP
37 signaling to initiate VoIP session;
- 38 • MUST use the visited network assigned address for
39 transmission of VoIP media packets, in order to optimize
40 routing (preclude media path tromboning)

1 5 REQUIREMENTS

2 The requirements for MMD policy enhancements are specified in
3 this section. Some illustrative examples are in Annex A.

4 5.1 Policy Contexts

5 5.1.1 Network-Level and User-Level Policies

6 User-level policies are those applied to a single user based on their
7 subscription. MMD shall provide capabilities to define and enforce
8 network-level and user-level policies at various states of device
9 operation (registration, handoff, change in access technology, and
10 other similar states) based on, but not limited to, the following:

- 11 • QoS constraints
- 12 • Accounting
- 13 • Mobility and Roaming
- 14 • Access Technology
- 15 • Authentication and Re-authentication
- 16 • Network Selection
- 17 • Traffic Engineering
- 18 • Resource Selection (e.g. routing optimization)
- 19 • Packet Flow Optimization
- 20 • Address Translation (to support NAT/Fire Wall (FW) Traversal)

21 5.2 Admission Control

22 5.2.1 IP Flow Admission

23 MMD shall provide support for admission control of IP flows.
24 Admission control includes congestion related decisions at the time
25 an application is invoked, based on, but not limited to, the
26 following:

- 27 • Network resource allocation and service differentiation (e.g.
28 differentiation between IP Television (TV) and Video
29 Telephony)
- 30 • An indication from the radio access network of the mobile
31 device availability status
- 32 • The characteristics of the mobile equipment, such as its
33 software version, screen size, and other similar
34 characteristics
- 35 • The subscription profile of the subscriber invoking the
36 application (e.g. preferential access based on subscription)
- 37 • Other applications that a subscriber has simultaneously
38 invoked (including SIP and non-SIP applications) based on
39 service characteristics and subscriptions

- 1 • The media makeup and bearer flows associated with the
- 2 application being invoked (e.g. audio, video)
- 3 • The QoS characteristics of the application (e.g.
- 4 conversational, streaming, interactive and background). See
- 5 reference [2].
- 6 • Time of day
- 7 • The characteristics of the content being delivered by the
- 8 service.

9 5.2.2 Access Network Selection

10 A multi-mode User Equipment (UE) shall work in concert with the
11 network to automatically determine which access technology (e.g.,
12 1x Radio Transmission Technology (1xRTT), Evolution Data only
13 (EVDO), WiFi) will be used at any given moment, based on factors
14 such as network policy (e.g. operator preferred roaming or peering
15 partners), RF conditions, QoS capabilities, and bandwidth
16 capabilities. The customer may be allowed to invoke a manual
17 override of access technology used (e.g., customer prefers WiFi).

18 5.2.3 QoS

19 MMD shall provide the capability for an application on an AT to
20 request QoS with specified characteristics, and admit the
21 application based on those characteristics.

22 5.2.4 Security Status

23 MMD shall provide the capability to make admission decisions at
24 the time an application is invoked based on the security status of
25 the mobile.

26 5.2.5 Roaming Status

27 MMD shall provide the capability to make admission decisions
28 based on the roaming status of a user, including, but not limited
29 to, the following:

- 30 • The identity of the user's visited network
- 31 • The geographic location where the user is roaming
- 32 • The technology of the visited access network (e.g. High Rate
- 33 Packet Data (HRPD), cdma2000, WiFi, DSL, etc.)

34 5.2.6 Network Status

35 When roaming, the visited network shall be able to make
36 admission decisions based on, but not limited to, the following:

- 37 • The types of network resources (QoS, accounting, etc.)
- 38 available to roaming users
- 39 • The amount of network resources (percentage of access
- 40 bandwidth, credit balance, etc.) available to roaming users.

- 1 • Whether network resources are granted to a visited
- 2 subscriber for better than best-effort service based on the
- 3 identity of the home provider
- 4 • SLA in effect with the home operator
- 5 • The type of invoked application (both SIP and non-SIP)
- 6 • Any home and local security restrictions

7 5.2.7 Third Parties Applications

8 MMD shall provide the capability for the network to make network-
9 resource allocation & charging decisions for applications that are
10 provided by third party applications.

11 5.2.8 IP Address Assignment when Roaming

12 MMD shall be capable of assigning an IP address to the roaming
13 UE based on permissions of its home operator's policy settings.

14 5.2.9 Resource Admission

15 The MMD resource admission control decision shall be subject to
16 policy control for both SIP and non-SIP applications.

17 5.2.10 Access to Services

18 MMD shall support the ability of the Network Service Provider
19 (NSP) to use the following to control the user's access to specific
20 services when the user is roaming: (1) service properties, (2)
21 operator policy specific to a roamed network, and (3) service profile
22 data.

23 **5.3 Policy Peering**

24 5.3.1 Service-Level Agreement

25 MMD shall provide the capability to support policy peering
26 relationships based on either SLAs between individual network
27 operators or network operators' mutual agreements with
28 clearinghouses. These peering relationships shall support the
29 exchange of policy/charging rules between the peered networks.

30 Note: There may be different aspects of peering, e.g.: IP-level,
31 policy, security, and application.

32 5.3.2 Media Traffic Routing

33 MMD shall provide the capability of the home network to decide,
34 on an application-by-application basis (both SIP and non-SIP)
35 whether or not the media traffic needs to be routed through the
36 home network. The visited network shall have the capability to
37 override home network policy decisions related to use of visited
38 network resources.

1 5.3.3 Roaming User Support

2 MMD shall enable the NSP to provide policy peering for SIP and
3 non-SIP applications with other providers for supporting roaming
4 users.

5 5.3.4 Home and Visited Network Control

6 MMD shall support policy peering to allow for both the home and
7 the visited network to exert policy control of resources used in the
8 visited network to meet subscriber expectations of service quality.

9 **5.4 Policy Management**

10 5.4.1 New Characteristics and Applications

11 MMD shall provide the capability to define new characteristics and
12 add new applications over time, and to define policies based on
13 those characteristics, along with a mechanism for managing these
14 policies.

15 5.4.2 Policy Consistency

16 MMD shall provide the mechanism for distributing consistent
17 policy and context across one or more domains to any network
18 element that participates in policy decisions or policy enforcement.

19 5.4.3 Hierarchical Policy Rules

20 MMD shall allow for a hierarchical set of policy rules. The policy
21 rules shall explicitly specify their precedence. The policy
22 enforcement point shall act in accordance with precedence of rules,
23 so that any conflict between them can be resolved.

24 5.4.4 Subscription Information

25 MMD shall provide the capability to base policy decisions upon
26 subscription information. The Policy and Charging architecture
27 should avoid duplication of subscription information relevant for
28 policy decisions.

29 5.4.5 Policy Change

30 The policy data repository function shall provide a mechanism
31 which allows relevant network elements to be informed about
32 policy changes.

33 5.4.6 New Services and Features

34 Changes to the policy peering interface between roaming partners
35 shall not be required when new services or features are introduced
36 in the home network.

1 5.4.7 Parental and Enterprise Control

2 MMD shall support parental/enterprise control by providing the
3 capability of an authorized entity (parent, corporate administrator,
4 etc.) to update the policy of a particular subscriber or set of
5 subscribers.

6 5.4.8 User Personalities

7 MMD shall support User Personalities by allowing a subscriber to
8 have multiple sets of policy and selecting a particular set in real
9 time based on various conditions such as signaling message
10 parameters and time of day.

11 5.4.9 Dynamic Policy Changes

12 MMD shall have the capability to change policy decisions after an
13 application has been invoked, based on changes in access
14 technology, time of day, location, & application-specific behaviors.

15 5.4.10 Emergency Services and Priority

16 MMD shall be capable of providing emergency services with QoS,
17 and priority treatment over existing calls, based on NSP policy.

18 **5.5 Authentication**

19 5.5.1 Trust Hierarchies and Horizontal Relationships

20 MMD shall provide the capability to define policies associated with
21 trust hierarchies and horizontal relationships between trust
22 domains. A trust domain is a collection of network elements
23 subject to a common set of security policies.

24 5.5.2 Credential Distribution

25 MMD shall provide the capability to define policies which govern
26 the distribution of security credentials across network elements.

27 5.5.3 Credential Expiration

28 MMD shall provide the capability to define policies that govern
29 expiration and refresh of security credentials.

30 5.5.4 Credential Information Exchange

31 MMD shall provide the capability to define policies that enable and
32 disable credential information exchange which support optional
33 authentication procedures.

34 **5.6 Privacy**

35 5.6.1 Asserted User Identities

36 In roaming and peering contexts, MMD shall be able to define and
37 manage the policy as to which asserted user identities may be

1 communicated between certain network entities in the same
2 network and exported from the home network to external
3 networks.

4 **Annex A Requirement Examples (Informative)**

5 This annex contains illustrative examples. The examples are not
6 exhaustive. Each example is linked to the corresponding
7 requirement by means of the associated paragraph number and
8 title. The paragraph numbers in the annex correspond to the
9 associated requirement in the body of the document.

10 **A.1 5.2.1 IP Flow Admission**

- 11 • An indication from the radio access network of the mobile
12 device availability status
13 Example: If a mobile device presence status is “not
14 available”, a Voice over IP (VoIP) attempt to that device
15 may be directed to a Voice Mail Server before
16 resources are committed to establish a VoIP session.
- 17 • The subscription profile of the subscriber invoking the
18 application (e.g. preferential access based on subscription)
19 Example: A VoIP session attempted by a priority user
20 may be admitted, while ordinary users’ attempted
21 sessions may be blocked.
- 22 • Other applications that a subscriber has simultaneously
23 invoked (including SIP and non-SIP applications) based on
24 service characteristics and subscriptions
25 Example: If a subscriber is in a VoIP session, adding a
26 multimedia streaming session may be disallowed while
27 congestions persists.
- 28 • The media makeup and bearer flows associated with the
29 application being invoked (e.g. audio, video)
30 Example: In cases of severe congestion, attempted
31 PSVT sessions may be curtailed to audio only.
- 32 • The QoS characteristics of the application (e.g.
33 conversational, streaming, interactive and background). See
34 reference [2].
35 Example: An application that is more delay tolerant
36 has lesser probability of being admitted, or visa-versa,
37 an application that is not delay tolerance has lesser
38 probability of being admitted. The operator can decide
39 to implement the policy either way.
- 40 • Time of day
41 Example: Admission regime may change depending on
42 the time of day. For example, a proportion of traffic
43 “reserved” for VoIP may be increased during the

1 traditional peak usage hours important for business
2 users.

- 3 • The characteristics of the content being delivered by the
4 service.

5 Example: Admission for users attempting to access
6 business-related content may be different than if the
7 content is of entertainment nature.

8 **A.2 5.2.6 Network Status**

- 9 • The amount of network resources (percentage of access
10 bandwidth, number of charging counters, etc.) available to
11 roaming users

12 Example: The visited network may impose admission
13 related policies to the roaming subscriber similar to
14 those enumerated in 5.2.1.

- 15 • SLA in effect with the home operator

16 Example: Based the identity of the home provider,
17 network resources granted to a visited subscriber may
18 be restricted to best-effort services only.

19 **A.3 5.4.1 New Characteristics and Applications**

20 Example: Introducing multimedia priority service for a certain
21 class of users may require new policies, such as preferential
22 admission. These new policies may require new mechanisms for
23 the policy implementation, such as priority treatment in SIP-aware
24 network elements.

25 **A.4 5.4.3 Hierarchical Policy Rules**

26 Example: Policy rule #1: In case of congestion, admission for high
27 latency applications (e.g. web browsing) shall be curtailed first, and
28 admission for real-time application last. Policy rule #2: Users
29 subscribed to multimedia priority services shall have preferential
30 admission. Let us assume that congestion occurs in the network,
31 so that high latency applications are not being admitted, e.g. all
32 but VoIP are being curtailed. If a multimedia priority service is
33 invoked for a high latency application, such as web browsing, the
34 priority subscriber is nevertheless admitted, i.e. rule #2 has
35 precedence over the rule #1.

36 **A.5 5.4.4 Subscription Information**

37 Example: Duplication of information that affects policy in PCRF
38 and HSS should be avoided. For example, if the PCRF contains
39 information that affects admission policy, any analogous
40 information should not be duplicated in the subscription profile in
41 the HSS.

42 **A.6 5.6.1 Asserted User Identities**

1 Example: A roaming subscriber's account with an adult content
2 channel is not revealed to the visited network by specific reference
3 to that subscriber's explicit public identity, though the fact that
4 special charging rules apply is revealed.
