Foreword

This specification has been produced within the Third Generation Partnership Project (3GPP), and has been elaborated by the TSG RAN WG1 working group, as a part of the work in defining and describing Layer 1 of the Universal Mobile Terrestrial Radio Access (UTRA).

This specification describes the physical layer procedures in UTRA/FDD.

1 Scope

This document specifies and establishes the characteristics of the physical layer procedures in the FDD mode of UTRA.

2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, subsequent revisions do apply.
- A non-specific reference to an ETS shall also be taken to refer to later versions published as an EN with the same number.

3 Definitions, symbols and abbreviations

3.1 Definitions

For the purposes of the present document, the following definitions apply:

<defined term>: <definition>.

3.2 Symbols

For the purposes of the present document, the following symbols apply:

<symbol> <Explanation>

3.3 Abbreviations

For the purposes of the present document, the following abbreviations apply:

BCH	Broadcast Channel
CCPCH	Common Control Physical Channel
DCH	Dedicated Channel
DPCCH	Dedicated Physical Control Channel
DPCH	Dedicated Physical Channel
DPDCH	Dedicated Physical Data Channel
FACH	Forward Access Channel
MUI	Mobile User Identifier
PCH	Paging Channel
PI	Paging Indication
PRACH	Physical Random Access Channel
RACH	Random Access Channel
SCH	Synchronisation Channel
SIR	Signal-to-Interference Ratio
SSDT	Site Selection Diversity TPC
TPC	Transmit Power Control
UE	User Equipment

4 Synchronisation procedures

4.1 Cell search

< Editor's note: The contents of this subclause is to a large extent information on how the UE could do the cell search, and can therefore be seen as more of informative material. Contents are taken from Volume 3 3.2.6.1 and XX.07 clause 5. Some details on how the receiver works that could be found in XX.07 has been left out. Mentioning of that it is the "strongest" cell that is searched for is left out, since the UE may not have access to the strongest cell. >

During the cell search, the UE searches for a cell and determines the downlink scrambling code and frame synchronisation of that cell. The cell search is typically carried out in three steps:

Step 1: Slot synchronisation

During the first step of the cell search procedure the UE uses the SCH's primary synchronisation code to acquire slot synchronisation to a cell. This is typically done with a single matched filter (or any similar device) matched to the primary synchronisation code which is common to all cells. The slot timing of the cell can be obtained by detecting peaks in the matched filter output.

Step 2: Frame synchronisation and code-group identification

During the second step of the cell search procedure, the UE uses the SCH's secondary synchronisation code to find frame synchronisation and identify the code group of the cell found in the first step. This is done by correlating the received signal with all possible secondary synchronisation code sequences, and identifying the maximum correlation value. Since the cyclic shifts of the sequences are unique the code group as well as the frame synchronisation is determined.

Step 3: Scrambling-code identification

During the third and last step of the cell search procedure, the UE determines the exact primary scrambling code used by the found cell. The primary scrambling code is typically identified through symbol-by-symbol correlation over the Primary CCPCH with all codes within the code group identified in the second step. After the primary scrambling code has been identified, the Primary CCPCH can be detected, super-frame synchronisation can be acquired and the system- and cell specific BCH information can be read.

If the UE has received a priority list with information about which scrambling codes to search for, steps 2 and 3 above can be simplified.

4.2 Primary CCPCH synchronisation

< Editor's note: The contents of this subclause comes from Volume 3 section 3.2.6.2.1. >

Synchronisation of the Primary CCPCHs is obtained during the cell search, see subclause 4.1 above. Frame synchronisation is obtained in step 2 of the cell search, and super-frame synchronisation is obtained by reading the SFN information on the BCH.

4.3 Secondary CCPCH synchronisation

< Editor's note: The contents of this subclause comes from Volume 3 section 3.2.6.2.2. >

Synchronisation of the Secondary CCPCHs can be obtained from the Primary CCPCH synchronisation and the timing offset information T_{CPCH} <ARIB terminology, to be confirmed> broadcast on the BCH. The frame timing and super-frame timing of the Secondary CCPCH is shifted by T_{CPCH} from the timing of the Primary CCPCH.

4.4 PRACH synchronisation

< Editor's note: This needs to be co-ordinated with the random access description. Contents of this subclause comes from Volume 3 section 3.2.5.1 and XX.03 subclause 5.2.2.1.1. >

Transmission of random access bursts on the PRACH is done aligned with access slot times. The timing of the access slots is derived from the received Primary CCPCH timing < Editor's note: In ARIB it is offset from the Secondary CCPCH. > The transmit timing of access slot n starts $n \times 10/N$ ms after the frame boundary of the received Primary CCPCH, where $n = 0, 1, \dots, N-1$, and N is the number of access slots per 10 ms.

4.5 DPCCH/DPDCH synchronisation

< Editor's note: The contents of this subclause comes from Volume 3 section 3.2.6.2.3.2 and 3.2.6.6.1, but the presentation of the material has been re-structured. >

4.5.1 General

The synchronisation of the dedicated physical channels can be divided into two cases:

- when a downlink dedicated physical channel and uplink dedicated physical channel shall be set up at the same time;
- or when a downlink dedicated physical channel shall be set up and there already exist an uplink dedicated physical channel.

The two cases are described in subclauses 5.5.1 and 5.5.2 respectively.

4.5.2 No existing uplink dedicated channel

The assumption for this case is that a DPCCH/DPDCH pair shall be set up in both uplink and downlink, and that there exist no uplink DPCCH/DPDCH already. This corresponds to the case when a dedicated physical channel is initially set up on a frequency.

< Editor's note: The actual procedure below is for the time being copied directly from Volume 3 section 3.2.6.2.3.2. The terminology should be updated in accordance with the rest of the specification. The figure should also be updated. This will be done in the next version of this document. >

The outline of synchronization establishment procedures of the dedicated physical channel is described below. The detailed synchronization establishment process flow is shown in Fig.3.2.6-1.

- (a) The BTS starts the transmission of forward link channels. TPC bits transmitted by BTS are predetermined pattern. DATA field on DPDCH is not transmitted when there is no data to be transmitted. DATA field on DPCCH is transmitted when there is data to be transmitted to MS.

- (b) The MS establishes forward link chip synchronization and frame synchronization based on the perch channel synchronization timing and the frame offset group, slot offset group notified from the network. The frame synchronization shall be confirmed using Frame Synchronization Word.
- (c) The MS starts the transmission of reverse link channel at the frame timing delayed by the slot offset from the forward link channel. DATA field on DPDCH is not transmitted when there is no data to be transmitted. DATA field on DPDCH is transmitted when there is data to be transmitted to BTS. Transmission power of reverse link channel follows the TPC bits transmitted by BTS. TPC bits transmitted by MS are based on forward link Eb/Io measurement results.

The MS informs upper layer of synchronization completion.

- (d) The BTS establishes reverse link channel chip synchronization and frame synchronization based on the frame offset group and slot offset group. The frame synchronization shall be confirmed using Frame Synchronization Word. In case of multi-code transmission, synchronisation establishment process may be done with one arbitrary physical channel. The actual synchronisation timing here will be shifted by the amount of round trip propagation delay time between the MS and BTS. Therefore, it is possible to shorten the search range for synchronisation establishment by using the round trip propagation delay time measured at the time of random access reception. After synchronisation is established, BTS informs upper layer of synchronization completion. Transmission power of forward link channel follow the TPC bits transmitted by MS. TPC bits transmitted by BTS are based on reverse link Eb/Io measurement results.

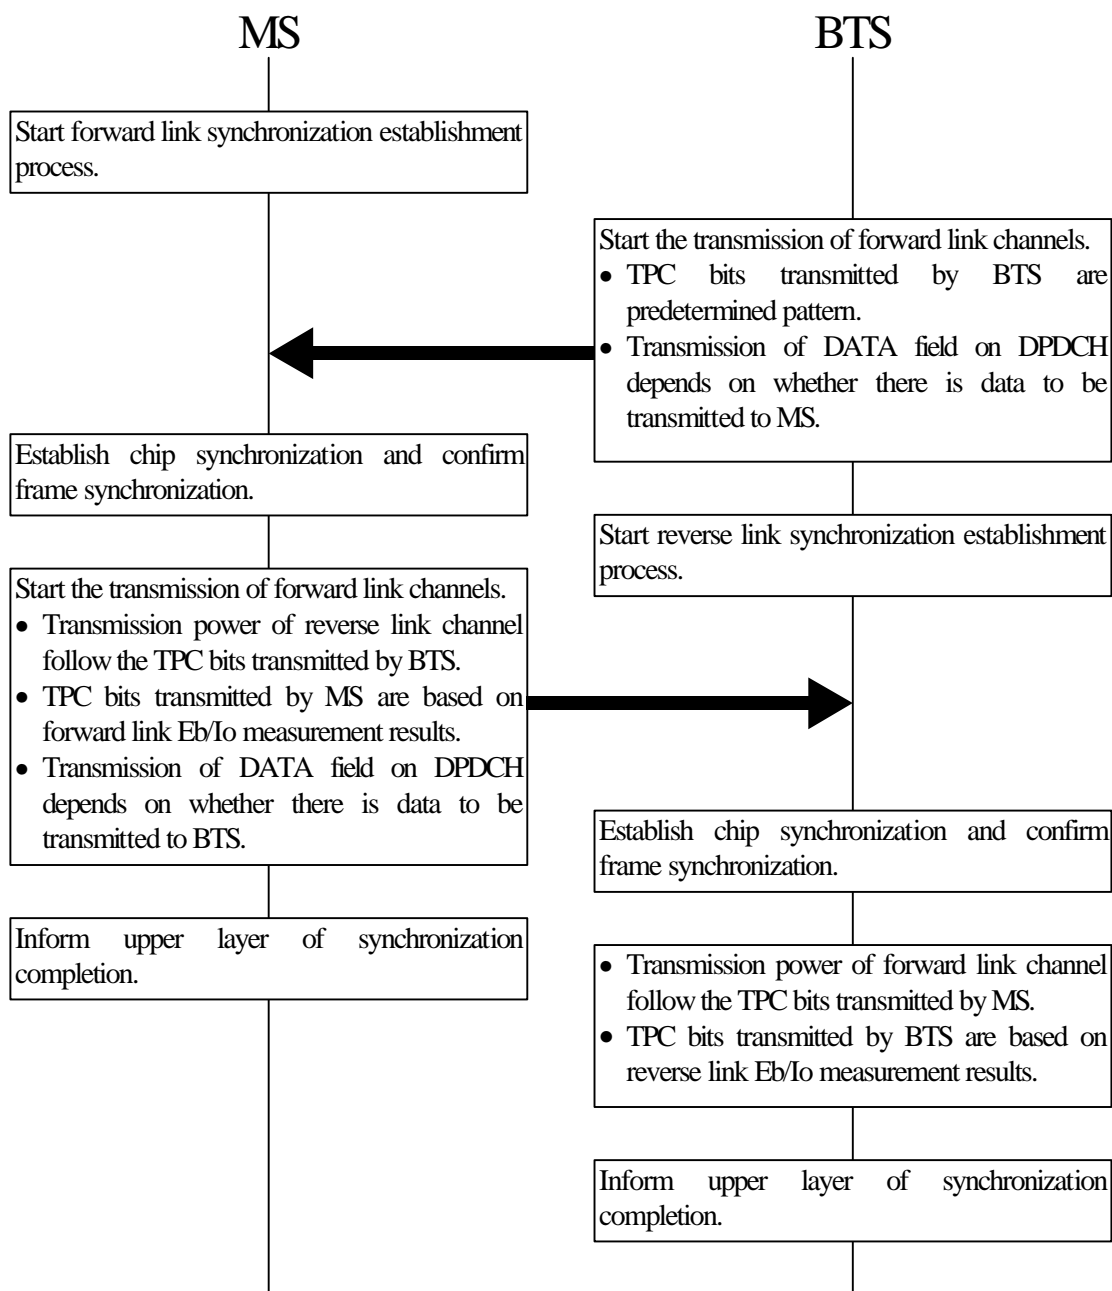

Fig.3.2.6-1 Synchronization Establishment Flow of Dedicated Channels

4.5.3 With existing uplink dedicated channel

The assumption for this case is that there already exist DPCCH/DPDCHs in the uplink, and a corresponding dedicated physical channel shall be set up in the downlink. This corresponds to the case when a new cell has been added to the active set in soft handover and shall begin its downlink transmission.

< Editor's note: The actual procedure below is based on the material in Volume 3 section 3.2.6.6.1. Material not relevant for L1 has been removed. The terminology should be updated in accordance with the rest of the specification. The figure should also be updated. This will be done in the next version of this document. >

At the start of diversity handover, the reverse link dedicated physical channel transmitted by the MS, and the forward link dedicated physical channel transmitted by the diversity handover source BTS will have their radio frame number and scrambling code phase counted up continuously as usual, and they will not change at all.

Naturally, the continuity of the user information mounted on them will also be guaranteed, and will not cause any interruption.

The synchronization timing upon starting diversity handover are presented in Fig. 3.2.5-4 < *Editor's note: Reference should be updated.* >. The synchronisation establishment flow upon intra/inter-cell diversity handover is described in Fig. 3.2.6-4.

- (a) The MS starts the chip synchronisation establishment process of forward link channel from the handover destination BTS with the notified radio parameters. The reverse link channels being transmitted shall continue transmission without any operations performed.
- (b) The BTS starts the transmission of forward link dedicated physical channels and starts the synchronization establishment process of reverse link dedicated physical channel transmitted by the MS. See chapter 3.2.5.1 < *Editor's note: Reference should be updated.* > for the specific transmission timing of forward link dedicated physical channels, and the reception timing of reverse link dedicated physical channel. As soon as chip synchronisation and frame synchronisation using Frame Synchronization Word are established, hard wired transmission shall be started.
- (c) Based on the handover destination perch channel reception timing, the MS establishes chip synchronisation of forward link channel from handover destination BTS. As soon as chip synchronisation is established, maximal ratio combining with the forward link channel from handover source BTS shall be started.

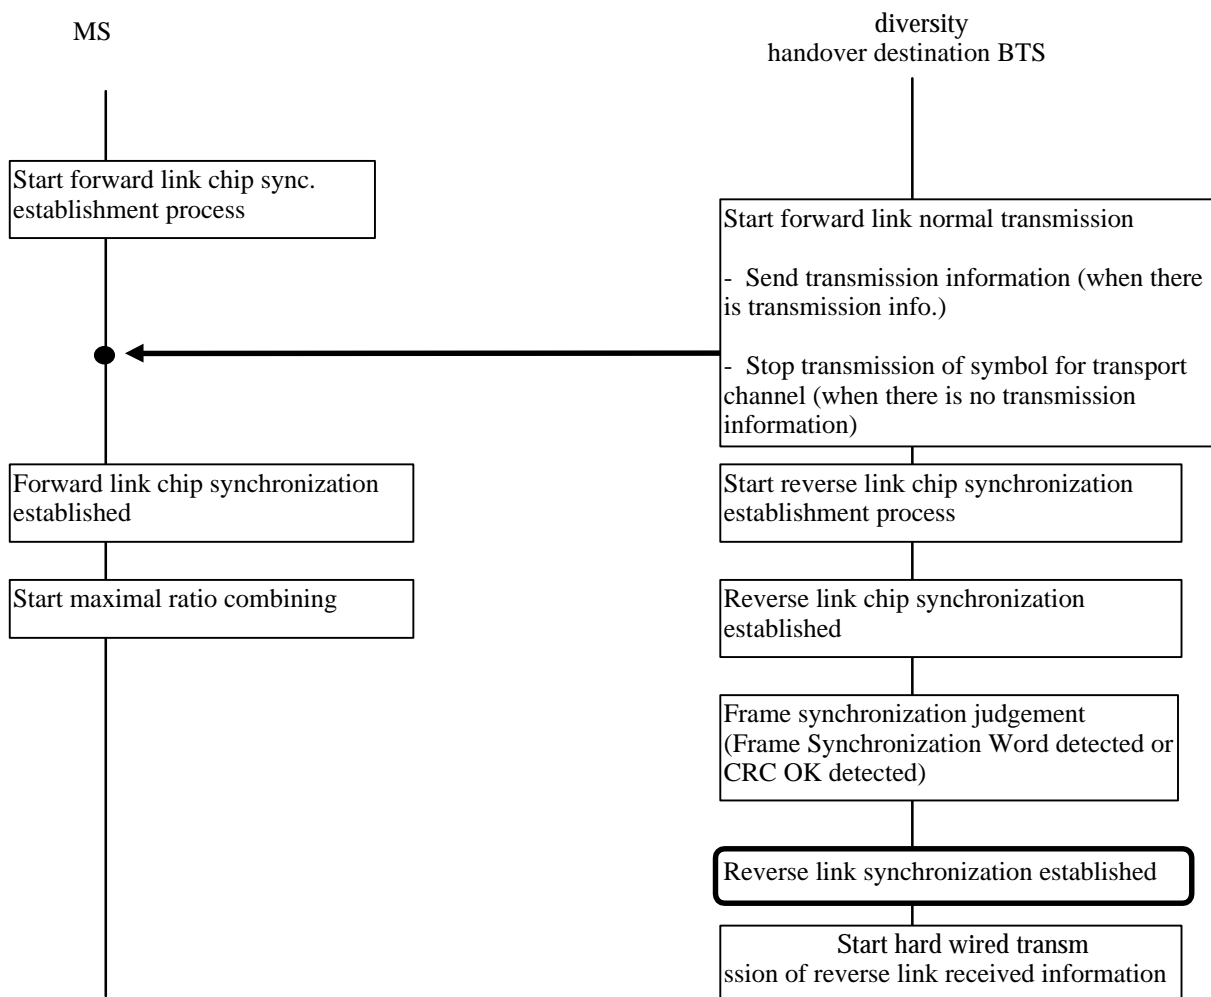

Fig. 3.2.6-4 Synchronization Establishment Flow Upon Intra/Inter-cell Diversity Handover

5 Power control

5.1 Uplink power control

5.1.1 PRACH

< Editor's note: To be confirmed after RACH ad hoc has come to a conclusion. Relevant section in Volume 3 is 3.2.6.7.1.1, and in XX.07 subclause 4.1.3 and clause 6. This may be mainly a matter for S1.15 to describe, since the open-loop power control is mainly a measurement to be done. However, the power setting based on the path-loss estimate is described in Volume 3, and this text is included below. >

- The transmitter power of MS shall be calculated by following equation:

$$P_{\text{RACH}} = L_{\text{Perch}} + I_{\text{BTS}} + \text{Constant value}$$

where,

P_{RACH} : transmitter power level in dBm,

L_{Perch} : measured path loss in dB,

I_{BTS} : interference signal power level at BTS in dBm, which is broadcasted on BCH,

Constant value: This value shall be designated via Layer 3 message (operator matter).

5.1.2 DPCCH/DPDCH

5.1.2.1 General

< Editor's note: Contents taken from Volume 3 section 3.2.6.7.1.2 and its subsections, and from XX.07 subclause 4.1.1.1 and its subclauses. >

The uplink transmit power control procedure controls simultaneously the power of a DPCCH and its corresponding DPDCHs. The power control loop adjusts the power of the DPCCH and DPDCHs with the same amount. The relative transmit power offset between DPCCH and DPDCHs is determined by the network and signalled to the UE using higher layer signalling.

5.1.2.2 Ordinary transmit power control

< Editor's note: Contents taken from Volume 3 section 3.2.6.7.1.2 and its subsections, and from XX.07 subclause 4.1.1.1 and its subclauses. >

5.1.2.2.1 General

The uplink closed-loop power control adjusts the UE transmit power in order to keep the received uplink signal-to-interference ratio (SIR) at a given SIR target, SIR_{target} . An higher layer outer loop adjusts SIR_{target} independently for each cell in the active set. < Editor's note: Details of outer loop left out, since it is a higher layer matter. Text can be found in Volume 3 section 3.2.6.7.1.2.2 and in XX.07 subclause 4.1.2. >

The serving cells (cells in the active set) should estimate the received uplink DPCCH power after RAKE combining of the connection to be power controlled. Simultaneously, the serving cells should estimate the total uplink received interference in the current frequency band and generate a SIR estimate SIR_{est} . The serving cells then generates TPC commands and transmits the commands once per 0.625 ms slot according to the following rule: if $SIR_{\text{est}} > SIR_{\text{target}}$ then the TPC command to transmit is "0", while if $SIR_{\text{est}} < SIR_{\text{target}}$ then the TPC command to transmit is "1".

< Editor's note: There is some confusion in XX.07 of the meaning of "0" and "1" TPC commands. Volume 3 is consistent, hence the above has been changed to what is in Volume 3. The rest of the text is then consistent. >

If multiple TPC commands are received, then upon reception of these TPC commands, the UE combines the received commands into a single TPC command, TPC_cmd. The combination process depends on whether the transmitted TPC commands are known to be the same or not. The combination process for each of these two cases is described in subclauses 5.1.2.2.2 and 5.1.2.2.3 respectively.

After calculation of the combined TPC command TPC_cmd , the UE then adjusts the transmit power of the uplink dedicated physical channels with a step of Δ_{TPC} dB according to the TPC command. If TPC_cmd equals 1 then the transmit power of the uplink DPCCCH and uplink DPDCHs shall be increased by Δ_{TPC} dB. If TPC_cmd equals 0 then the transmit power of the uplink DPCCCH and uplink DPDCHs shall be decreased by Δ_{TPC} dB.

< Editor's note: In Volume 3, it is stated that the time for changing transmit power shall be immediately before the pilot block. This is linked to slot structure (ad hoc 7), and could be described in S1.11. >

The step size Δ_{TPC} is a parameter that may differ between different cells, in the region 0,25 – 1,5 dB. < Editor's note: In Volume 3 Δ_{TPC} is fixed to 1 dB, this is discussed by the power control ad hoc. > In the event different step sizes are used in the different serving cells, then the transmit power change should take into account the TPC command obtained by combining individual commands and the different step sizes, and should be one of the allowed step sizes (FFS).

< Editor's note: The information in the paragraphs below is found in Volume 3 only. >

The initial uplink transmit power to use is decided using an open-loop power estimate, similar to the random access procedure. < This needs to be elaborated later on. How is the estimate derived? >

If the TPC commands cannot be received due to downlink out-of-synchronisation, the transmit power shall be kept constant. When SIR measurements cannot be performed due to uplink out-of-synchronisation, the TPC command transmitted shall be set as "1" during the period of out-of-synchronisation.

The maximum transmission power at the maximum rate of DPDCH is designated for uplink and control must be performed within this range. < Editor's note: Clarification needed, what does this mean? > The maximum transmit power value of the closed-loop TPC is set by the network using higher layer signalling.

The ordinary transmit power control of uplink dedicated physical channels is summarised in Figure 1 below. < Editor's note: The figure is taken directly from Volume 3. If it is felt necessary to keep the figure it should be updated to be in-line with the text. >

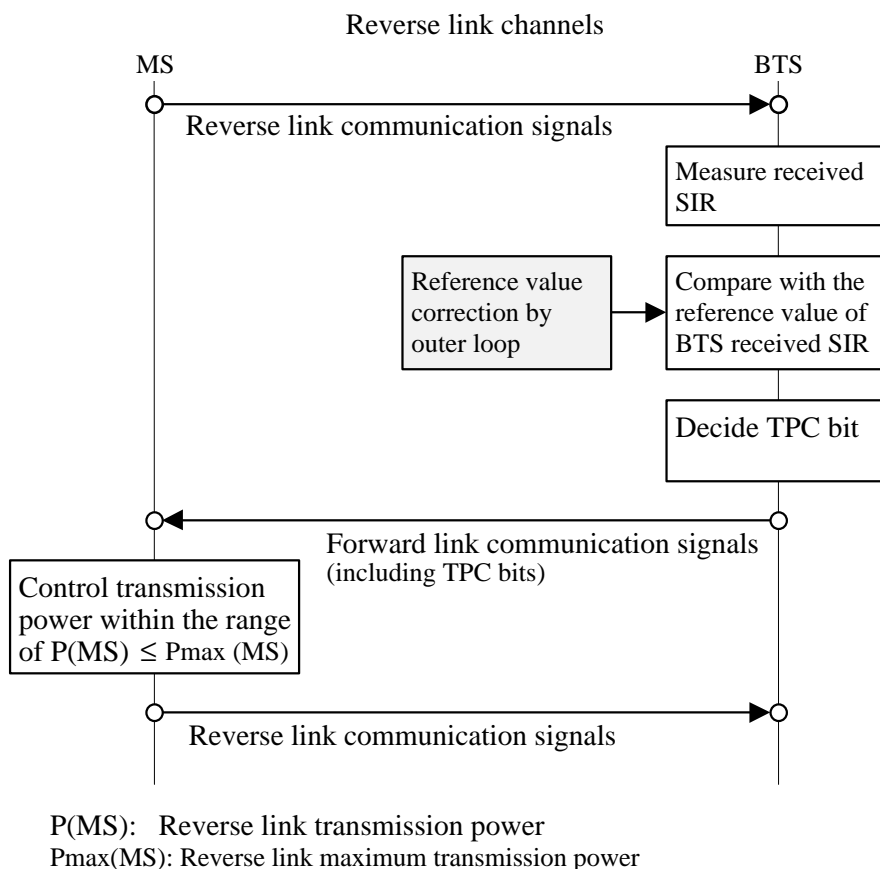

Figure 1

5.1.2.2.2 Combining of TPC commands known to be the same

In some cases, the UE has the knowledge that some of the transmitted TPC commands are the same. This is the case e.g. with receiver diversity or so called softer handover when the UTRAN transmits the same command in all the serving cells the UE is in softer handover with. For these cases, the TPC commands known to be the same are maximum ratio combined into one TPC command, to be further combined with other TPC commands as described in subclause 5.1.2.2.3.

5.1.2.2.3 Combining of TPC commands not known to be the same

In general in case of soft handover, the TPC commands transmitted in the different cells may be different.

This subclause describes the general scheme for combination of the TPC commands known to be different and then provides an example of such scheme. It is to be further decided what should be subject to detailed standardisation, depending on final requirements. The example might be considered as the scheme from which minimum requirement will be derived or may become the mandatory algorithm.

5.1.2.2.3.1 General scheme

First, the UE shall estimate the signal-to-interference ratio PC_SIR_i on each of the power control command TPC_i , where $i = 1, 2, \dots, N$ and N is the number of TPC commands known to be different, that may be the results of a first phase of combination according to subclause 5.1.2.2.3.

Then the UE assigns to each of the TPC_i command a reliability figure W_i , where W_i is a function β of PC_SIR_i , $W_i = \beta(PC_SIR_i)$. Finally, the UE derives a combined TPC command, TPC_cmd , as a function γ of all the N power control commands TPC_i and reliability estimates W_i :

$TPC_cmd = \gamma(W_1, W_2, \dots, W_N, TPC_1, TPC_2, \dots, TPC_N)$, where TPC_cmd can take the values 0 or 1.

5.1.2.2.3.2 Example of the scheme

A particular example of the scheme is obtained when using the following definition of the functions β and γ :

For β : the reliability figure W_i is set to 0 if $PC_SIR_i < PC_thr$, otherwise W_i is set to 1. This means that the power control command is assumed unreliable if the signal-to-interference ratio of the TPC commands is lower than a minimum value PC_thr .

For γ : if there is at least one TPC_i command, for which $W_i = 1$ and $TPC_i = 0$, then TPC_cmd is set to 0, otherwise TPC_cmd is set to 1. Such a function γ means that the power is decreased if at least one cell for which the reliability criterion is satisfied asks for a power decrease.

< Editor's note: This particular example of the more general scheme corresponds to the text in Volume 3. >

5.2 Downlink power control

5.2.1 Primary CCPCH

< Editor's note: Taken from Volume 3 section 3.2.6.7.2. >

< Editor's note: An assumption that the TX power of the primary CCPCH can be changed on a slow basis was made. It is not clear from the descriptions. The editor could see no reason why the power could not be changed. To be confirmed. Maybe this subclause can be skipped altogether, since it introduces no extra constraints over those described in higher layer specifications. >

The Primary CCPCH transmit power can vary on a slow basis, i.e. the power is constant over many frames. The transmit power is determined by the network and signalled on the BCH.

< Editor's note: In Volume 3 it is said that the power of the search codes is set independently from the Perch channel. Depending on the decision of the SCH multiplexing ad hoc, this may need to be reflected in the text. If there is no constraints on the SCH, should that be mentioned here? >

5.2.2 Secondary CCPCH

< Editor's note: Taken from Volume 3 section 3.2.6.7.2. >

The Secondary CCPCH transmit power is set by the network, and may vary.

< Editor's note: The following is taken from Volume 3 section 3.2.6.7.2 and may need some further elaboration. What quality information is meant? Is this layer 1 issue at all? >

In case that a sequence of message exchange between the network and a UE takes place, the network shall adjust transmission power based on the quality information included in the uplink. The transmission power shall be adjusted message by message. The network informs the transmission level to the UE so that the UE can adjust its transmission power.

5.2.3 DPCCH/DPDCH

5.2.3.1 General

The downlink transmit power control procedure controls simultaneously the power of a DPCCH and its corresponding DPDCHs. The power control loop adjusts the power of the DPCCH and DPDCHs with the same amount, i.e. the relative power difference between the DPCCH and DPDCHs is not changed.

< Editor's note: The possibility to have power offsets for the DPCCH fields relative to the DPDCH has been discussed but not adopted so far in ETSI. In ARIB this possibility already exist in the specification. This is discussed in ad hoc 7. Until this issue is decided, the contents of the ARIB scheme is kept in brackets below. >

[The relative transmit power offset between DPCCH fields and DPDCHs is determined by the network and signalled to the UE using higher layer signalling. The TFCI, TPC and pilot fields of the DPCCH are offset relative to the DPDCHs power by PO1, PO2 and PO3 dB respectively.]

5.2.3.2 Ordinary transmit power control

The downlink closed-loop power control adjusts the network transmit power in order to keep the received downlink SIR at a given SIR target, SIR_{target} . A higher layer outer loop adjusts SIR_{target} independently for each connection. < Editor's note: Details of outer loop left out, since it is a higher layer matter. Text can be found in Volume 3 section 3.2.6.7.2 and in XX.07 section 4.2.2. >

The UE should estimate the received downlink DPCCH/DPDCH power after RAKE combining, including diversity combining, of the connection to be power controlled. Simultaneously, the UE should estimate the received interference. < Editor's note: In XX.07 it says "should estimate the total downlink received interference in the current frequency band", but that cannot be correct because such a measurement does not take orthogonality into account. The details of the SIR measurement needs to be specified more in detail. > The obtained SIR estimate SIR_{est} is then used by the UE to generate TPC commands according to the following rule: if $SIR_{est} > SIR_{target}$ then the TPC command to transmit is "0", requesting a transmit power decrease, while if $SIR_{est} < SIR_{target}$ then the TPC command to transmit is "1", requesting a transmit power increase.

< Editor's note: How the SIR estimate should be derived is to be specified, in particular how it should be done for the case with power offsets on the DPCCH. >

The TPC command generated is transmitted in the first available TPC field in the uplink DPCCH.

< Editor's note: In Volume 3, the behaviour of the network is only given as examples. This leaves full freedom for the network to decide how to respond to the TPC commands received. However, in XX.07 more information about the networks behaviour is given: "Upon the reception of a TPC command, the network should adjust the transmit power in the given direction with a step of D_{TPC} dB. The step size D_{TPC} is a parameter that may differ between different cells, in the range 0,25 – 1,5 dB.". It is the view of the editor that the implementation of the network behaviour is not subject to standardisation. To be confirmed. >

< Editor's note: UE procedures in downlink out-of-synchronisation state should be specified. This is not done clearly in Volume 3, and is not mentioned in XX.07. However, a similar procedure as for uplink power control is indicated, and included below. >

When SIR measurements cannot be performed due to downlink out-of-synchronisation, the TPC command transmitted shall be set as "1" during the period of out-of-synchronisation.

< Editor's note: In Volume 3 it is also described how the power should be controlled during link set-up. This should probably be described in the synchronisation clause, so that the information is not repeated in several places. >

The ordinary transmit power control of uplink dedicated physical channels is summarised in Figure 2 below. < Editor's note: The figure is taken directly from Volume 3. If it is felt necessary to keep the figure it should be updated to be in-line with the text. >

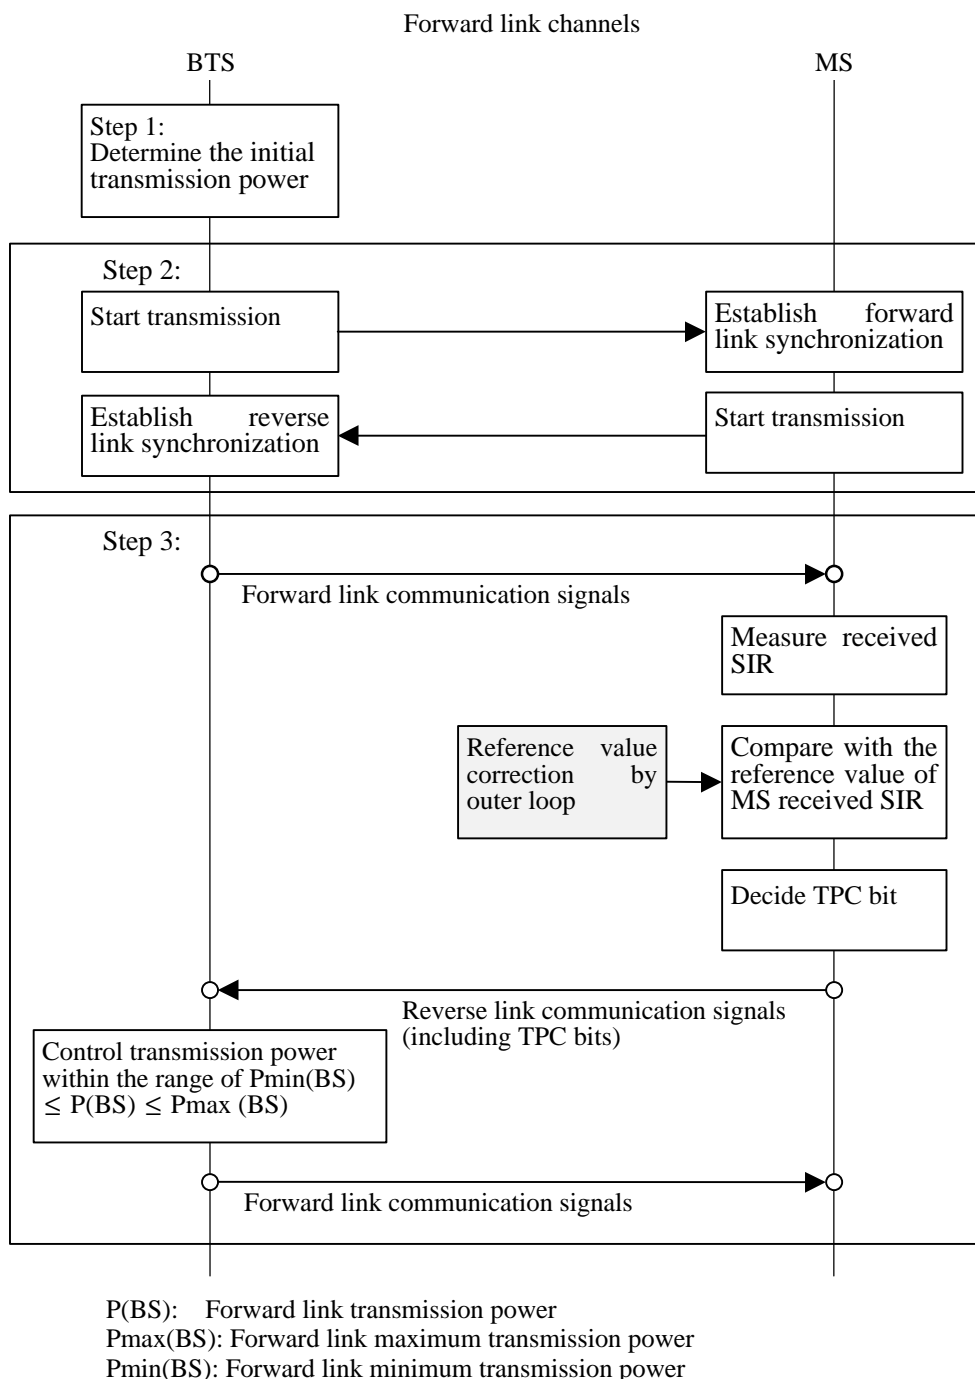

Figure 2

5.2.3.3 Slow transmit power control

< Editor's note: Only described in ARIB, Volume 3 section 3.2.6.7.2 2b. Text modified, but same contents. >

Following an order from the network and acknowledgement by the UE, ordinary fast closed-loop transmit power control can be stopped and a slow transmit power control mode can be entered. In this mode, downlink DPCCH/DPDCH transmit power is determined utilising power control ratios reported from the UE once per frame. Uplink transmission is suspended when the UE does not have any information to send, and the transmission is resumed to send a power control ratio at least once in every T_{RINT} second. < *Editor's note: What does this really mean? Needs more elaboration.* > The UE calculates power control ratios in the following steps:

1. The UE measures the per channel power of the cell in which the UE is located, and sets the value to Q_1 .
2. The UE measures per channel powers received from neighbouring cells, and sets the values greater than Q_1/R_{SEARCH} to Q_i , where $i = 2, 3, \dots, n$.
3. The UE sets the power control ratio to $(Q_1 + Q_2 + \dots + Q_n)/Q_1$.

All TPC bits in the uplink DPCCH are used to send power control ratios. One power control ratio is sent per frame, i.e. 32 TPC bits are used to carry the power control ratio. The bi-orthogonal (32,6) code described in subclause < *Update reference 3.2.4.2.1.1.1, and following notation* > is used for the encoding. Code word $(-1)^n C5(m)$ corresponds to $(0,5m + 0,25n)$ dB where $m = 0, 1, 2, \dots, 31$ and $n = 0, 1$.

Following an order from the network, the slow transmit power control is stopped and ordinary fast closed-loop transmit power control is started. The parameters T_{RINT} and R_{SEARCH} are set using higher layer signalling.

5.2.3.4 Site selection diversity transmit power control

< *Editor's note: This comes from Volume 3 section 3.2.6.7.2 and XX.07 subclause 4.2.3. The text in those sections is very similar, with only small differences. The text below is based on the XX.07 text. Any references to "RNC" has been replaced by references to "network", trying to not interfere with WG2 matters.* >

< *Editor's note: In general, the text describing SSDT should be checked to identify L1 and L23 issues separately. Some contents should perhaps be moved to WG2 documentation. The text could also be made more specification-like. For the time being the text is kept with some cosmetic and language related changes.* >

5.2.3.4.1 General

Site selection diversity transmit power control (SSDT) is an optional macro diversity method in soft handover mode.

Operation is summarised as follows. The UE selects one of the cells from its active set to be 'primary', all other cells are classed as 'non primary'. The main objective is to transmit on the downlink from the best cell, thus reducing the interference caused by multiple transmissions in a soft handover mode. A second objective is to achieve fast site selection without network intervention, thus maintaining the advantage of the soft handover. In order to select a primary cell, each cell is assigned a temporary identification and UE periodically informs a primary cell identification to the connecting cells. The non-primary cells selected by UE switch off the transmission power. The primary cell identity code is delivered via vacant uplink TPC bits prepared by the puncture method described in subclause 5.2.3.4.6.

5.2.3.4.2 Initiation of SSDT

The SSDT is initiated by the network, based on the soft handover active cell set. The cell and UE are subsequently informed by the network that the SSDT option has been activated during the current soft handover period. Otherwise, TPC is operated in the ordinary mode, i.e. each cell controls its power in accordance with an uplink TPC command by the way described in 5.2.3.2. The temporary cell identification assignment (i.e. ID code assignment) is based on the order of active set which is communicated to all the active cells and the UE.

A cell receiving the active list is capable of recognising its entry position in the list from which it can determine its own ID code. Similarly, UE upon receiving the active list can determine the ID code of each of the active cells according to the order of the cell entries in the list. Therefore the network and UE has the same association between the ID codes and cells. After the activation of the SSDT and the subsequent UE acknowledgements, the UE starts to send the "primary" cell ID code, described in the following subclauses. Following a successful activation of SSDT and reception of the UE acknowledgement, the active cells start detecting the "primary" cell ID information.

5.2.3.4.3 Settings of temporary cell identification

Each cell is given a temporary identification during SSDT and the identification is utilised as site selection signal. In the following, the temporary identification is referred to as "ID".

5.2.3.4.3.1 Definition of temporary cell identification

The ID is given a binary bit sequence with the length of N_{BID} bits. The parameter N_{BID} can take the value 4 or 8 bits. Setting examples of ID codes are exhibited in Table 1.

Table 1: Setting examples of ID codes

ID label	ID code	
	$N_{\text{BID}}=8$	$N_{\text{BID}}=4$
a	00000000	0000
b	11111111	1111
c	00001111	0011
d	11110000	1100
e	00111100	0110
f	11000011	1001

5.2.3.4.3.2 Assignment of ID to each cell

The "ID" word assignment is based on the entry position in the active list, which is compiled and communicated to all active cells and UE.

Table 2: ID assignment example

Number of cells in active set	ID label assignment for each cell					
	Entry position in active set					
	1	2	3	4	5	6
1	a					
2	a	b				
3	a	b	c			
4	a	b	c	d		
5	a	b	c	d	e	
6	a	b	c	d	e	f

5.2.3.4.3.3 Notification of ID assignment change

Every time that the active list is changed, it is updated and communicated to all active cells and UE.

5.2.3.4.4 TPC procedure in UE

The TPC procedure of the UE in SSDT is identical to that described in subclause 5.2.3.2.

5.2.3.4.5 Selection of primary cell

The UE selects a primary cell periodically by measuring reception levels of common pilots transmitted by the active cells. The cell with the highest pilot power is detected as a primary cell.

5.2.3.4.6 Delivery of primary cell ID

The UE periodically sends the ID code of the primary cell via vacant TPC bits given by the puncture method described here. A cell recognises its state as non-primary if the following two conditions are fulfilled simultaneously:

- the received primary ID code does not match with the own ID code,
- and the received uplink signal quality satisfies a quality threshold, Q_{th} , a parameter defined by the network.

Otherwise the cell recognises its state as primary.

At the UE, the primary ID code to be sent to the cells is segmented into a number of portions. These portions are distributed in the vacant TPC bit fields given by the puncture method. The cell in SSDT collects the distributed portions of the primary ID code and then detects the transmitted ID. There are two TPC puncture methods as shown in Table 3.

Table 3: TPC puncturing methods

	Number of punctured bits in a TPC symbol	Period of puncturing	Period of primary cell update	
			8 bit ID code	4 bit ID code
Case 1	1 bit	Every slot	Every 8 slots	Every 4 slots
Case 2	2 bits	Every 4 slots	Every 16 slots	Every 8 slots

In case 1, one bit of one TPC symbol is punctured every slot and thus, for example, it takes 8 slots to send 8 bit ID code. In case 2, 2 bits of one TPC symbol are punctured every 4 slots.

5.2.3.4.7 TPC procedure in the network

In SSDT, a non-primary cell can switch off its output power (i.e. no transmissions). TPC bits carrying portion of the primary ID code should be neglected in detecting power up / down signal. If the entire TPC symbol within a slot has been replaced by the portion of primary ID code, the downlink transmission power in the corresponding slot should hold the previous one.

5.2.3.4.7.1 Management of multiple transmission power levels

The cell manages two transmission power levels, P1, and P2. A cell keeping minimum power level would know the required transmit power by referring to P1 if selected as the primary cell. A cell updates P1 regardless of the selected choice. Level P2 is the actual transmission power level for non-primary cell. When a cell is selected by the UE as the primary cell, P2 is set to P1, otherwise the cell maintains P2 at the minimum transmit level (i.e. switched off). P1 and P2, expressed in dBm, are updated in accordance with TPC commands from the UE as shown in Table 4. The two power settings P1 and P2 are maintained within the power control dynamic range.

Table 4: Updating of P1 and P2

State of cell	TPC signal	P1	P2
non primary	down	$P1 - \Delta_{TPC}$	Switched off
	up	$P1 + \Delta_{TPC}$	Switched off
primary	down	$P1 - \Delta_{TPC}$	= P1
	up	$P1 + \Delta_{TPC}$	= P1

Δ_{TPC} is defined in subclause 5.2.3.2. < Editor's note: Maybe it is not defined in standard, see comment in 5.2.3.2. > No regulation of initial value of P1 and P2 is given.

< Editor's note: In Volume 3 several power levels are managed by the network. This was not accepted in ETSI so far. The outcome of the discussion on DPCCH field offsets should have impact on this issue as well. For the time being the ETSI text is kept.>

5.2.3.4.7.2 Power setting of the downlink Dedicated Physical Channel

The downlink Dedicated Physical Channel is partitioned into 4 portions as shown in < Editor's note: The reference needs to be updated, and the figure may need updating depending on the contents in S1.11. >. Power setting of each portion during SSDT is depicted in Figure 3.

Figure 3: Power setting of the downlink Dedicated Physical Channel

Transmission power of the TPC and TFI portions are always set to P1, in order to detect the control information at the UE with high reliability.

< Editor's note: In Volume 3 several power levels are managed by the network. This was not accepted in ETSI so far. The outcome of the discussion on DPCCCH field offsets should have impact on this issue as well. For the time being the ETSI text is kept. >

5.2.3.4.8 Termination of SSDT

The decision to terminate the SSDT is made by the network, based on the UE reported received signal strength levels of all the active and candidate list pilots. The termination request should be informed by the network to both cells and UE in the same way as soft handoff termination process.

6 Random access procedure

< Editor's note: The following clause is put in brackets until the random access ad hoc has come with a recommendation. >

[The procedure of a random access request is:

1. The UE acquires synchronisation to a cell
2. The UE reads the BCH to get information about:
 - 2.1 The preamble spreading code(s) / message scrambling code(s) used in the cell
 - 2.2 The available signatures
 - 2.3 The available access slots
 - 2.4 The available spreading factors for the message part
 - 2.5 The uplink interference level in the cell
 - 2.6 The primary CCPCH transmit power level
3. The UE selects a preamble spreading code/message scrambling code
4. The UE selects a spreading factor for the message part.
5. The UE estimates the downlink path loss (by using information about the transmitted and received power level of the primary CCPCH), and determines the required uplink transmit power (by using information about the uplink interference level in the cell).
- 6 The mobile implements the dynamic persistence algorithm by:
 - 6.1. Reading the current dynamic persistence value from the BCH.
 - 6.2. Perform a random draw against the current dynamic persistence value.
 - 6.3. Defer transmission for one frame and repeat step 6 if the result of the random draw is negative, otherwise proceed to step 7.
7. The UE randomly selects an access slot and signature from the available access slots and signatures.

8. The UE transmits its preamble.
9. If the UE does not detect an acquisition indicator with the selected signature in the next access slot, the UE retransmits the preamble with a re-selected signature in the next available access slot with a pre-defined change of transmit power and repeat step 9.
- 10 The UE transmits its random access message in the next available access slot.
11. The UE waits for an acknowledgement from the network side. If no acknowledgement is received within a predefined time-out period, the UE starts again from step 5.

Dynamic persistence is provided for managing interference and minimising delay by controlling access to the RACH channel. The system will publish a dynamic persistence value on the BCH, the value of which is dependent on the estimated backlog of users in the system.]

7 Transmission stop and resumption control

< Editor's note: The contents of this clause have been taken from Volume 3 section 3.2.6.9.2. No corresponding section exists in XX.07 or any other XX-document. In the subclauses below, the technical contents of the Volume 3 text has been kept, but the text is rewritten in an attempt to improve readability. >

7.1 General

< Editor's note: The contents of this subclause have been taken from Volume 3 section 3.2.6.9.2. >

On dedicated physical channels, when no higher layer data exist to transmit, the DPDCH is empty and is not transmitted. In order to save channel capacity, under some conditions the transmission of the DPCCH can also be stopped. Similarly, conditions are also defined for how the transmission of DPCCH/DPDCH is resumed.

< Editor's note: From Volume 3 figure 3.2.6-16 it seems that the transmission stop scheme is only applicable when the other link do not transmit a DPDCH, while this is not explained in the text. Clarification is needed on this point. >

7.2 Transmission stop control

7.2.1 Network control procedure

< Editor's note: The contents of this subclause have been taken from Volume 3 section 3.2.6.9.2.1. >

The necessity of downlink DPCCH/DPDCH transmission is judged in each radio frame. When the DPDCH is stopped, i.e. there is no data to transmit on the DPDCH, the network continues to transmit the DPCCH until either

- Fkp-f radio frames have passed after the DPDCH transmission was stopped,
- or Fcrc-b radio frames are detected consecutively with no correct CRC in uplink,

when the DPCCH transmission is stopped as well.

The parameters Fkp-f [= 2] and Fcrc-b [= 2] are set by higher layer procedures.

7.2.2 UE control procedure

< Editor's note: The contents of this subclause have been taken from Volume 3 section 3.2.6.9.2.1. >

The necessity of uplink DPCCH/DPDCH transmission is judged in each radio frame. When the DPDCH is stopped, i.e. there is no data to transmit on the DPDCH, the UE continues to transmit the DPCCH until either

- Fkp-b radio frames have passed after the DPDCH transmission was stopped,
- or the downlink is detected to be out-of-synchronisation,

when the DPCCH transmission is stopped as well.

The parameter $F_{kp-b} [= 2]$ is set by higher layer procedures.

7.2.3 Illustration of network and UE procedures

< Editor's note: The contents of this subclause have been taken from Volume 3 figure 3.2.6-16. >

Figure 4 illustrates the scheme for the case where there exist a DPCCH/DPDCH in downlink and a DPCCH in uplink, and transmission of the downlink DPDCH is stopped.

Figure 4: Transmission stop control when downlink DPDCH is stopped

Figure 5 illustrates the scheme for the case where there exist a DPCCH/DPDCH in uplink and a DPCCH in downlink, and transmission of the uplink DPDCH is stopped.

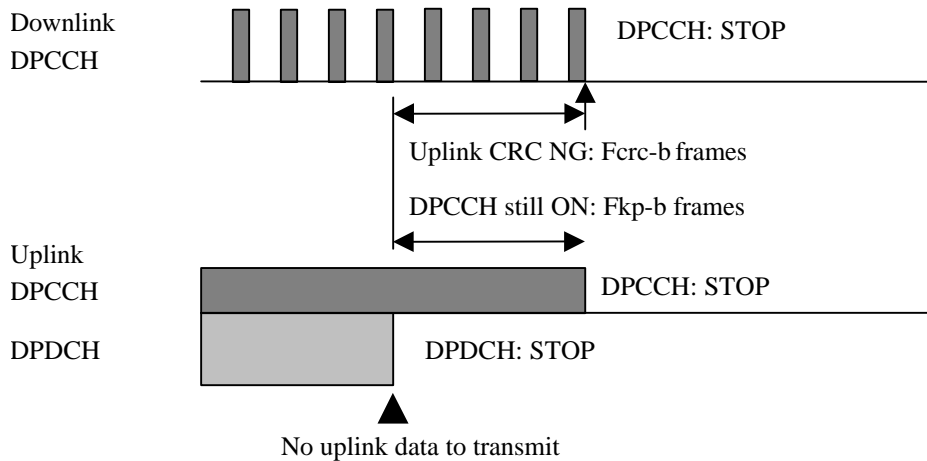

Figure 5: Transmission stop control when uplink DPDCH is stopped

7.3 Transmission resumption control

7.3.1 Network control procedure

< Editor's note: The contents of this subclause have been taken from Volume 3 section 3.2.6.9.2.2. >

Suspended downlink DPCCH/DPDCH transmission is resumed if data to be transmitted on the DPDCH arrives. < Editor's note: Arrives where? Probably not at L1, since having buffering of several frames at L1 is unwanted. Maybe the control of the resumption is a higher layer procedure. This issue needs clarification. > When resuming DPDCH transmission, the network transmits dummy frames prior to radio frames with real data.

The number of dummy frames to transmit is F_{tr} . If the number of frames after pausing transmission < *Editor's note: after pausing DPCCH or DPDCH?* > is less than F_{gap} , where chip and frame synchronisation is expected to be kept, the dummy frames consist of only DPCCH (pilot and TPC) transmitted in the last Str slots of each dummy frame. If the number of frames after pausing transmission is more than F_{gap} , the dummy frames consist of both DPCCH and DPDCH parts, where all of the CRC coding field shall be set to 0, and the TPC commands are set to a predetermined pattern, for example indicating transmission power increase. < *Editor's note: The last sentence needs to be clarified, what is meant by setting the CRC coding field to 0?* >

The network selects an initial transmission power to be used when starting to send the dummy frames, and increases its transmission power by P_{up} dB in each Sup slots until receiving the DPCCH in the uplink, but the maximum transmission power is limited to P_{max} dBm. After sending the dummy frames, closed-loop power control is applied to the downlink transmission as described in subclause 5.2.3.

Also, suspended downlink DPCCH transmission is resumed when synchronisation is established with the corresponding uplink dedicated physical channel that was previously in out-of-synchronisation. When DPCCH transmission is resumed the network selects an initial transmission power to be used, and applies closed-loop power control to the downlink transmission as described in subclause 5.2.3.

The parameters F_{tr} [=2], Sup [=4], P_{up} [= 1], P_{max} , F_{gap} [= 2], Str [= 4] are set by higher layer procedures. The values of these parameters may be set differently between network and UE.

< *Editor's note: The parameter P_{add} was removed, since it is anyway up to the network to set the initial power as it wishes.* >

7.3.2 UE control procedure

< *Editor's note: The contents of this subclause have been taken from Volume 3 section 3.2.6.9.2.2.* >

< *Editor's note: Very similar to network control procedure, and the same questions raised in that subclause applies here as well.* >

Suspended uplink DPCCH/DPDCH transmission is resumed if data to be transmitted on the DPDCH arrives. When resuming DPDCH transmission, the UE transmits dummy frames prior to radio frames with real data.

The number of dummy frames to transmit is F_{tr} . If the number of frames after pausing transmission is less than F_{gap} , where chip and frame synchronisation is expected to be kept, the dummy frames consist of only DPCCH (pilot and TPC) transmitted in the last Str slots of each dummy frame. If the number of frames after pausing transmission is more than F_{gap} , the dummy frames consist of both DPCCH and DPDCH parts, where all of the CRC coding field shall be set to 0, and the TPC commands are set to a predetermined pattern, for example indicating transmission power increase.

Using an open-loop transmit power estimate similar to the one described in subclause 5.1.1, the UE derives an initial transmission power to be used when starting to send the dummy frames, and increases its transmission power by P_{up} dB in each Sup slots until receiving the DPCCH in the downlink, but the maximum transmission power is limited to P_{max} dBm. After sending the dummy frames, closed-loop power control is applied to the uplink transmission as described in subclause 5.1.2.

Also, suspended uplink DPCCH transmission is resumed when synchronisation is established with the corresponding downlink dedicated physical channel that was previously in out-of-synchronisation. When DPCCH transmission is resumed the UE selects an initial transmission power to be used based on an open-loop transmit power estimate similar to the one described in subclause 5.1.1, and applies closed-loop power control to the uplink transmission as described in subclause 5.1.2.

The parameters F_{tr} [=2], Sup [=4], P_{up} [= 1], P_{max} , F_{gap} [= 2], Str [= 4] are set by higher layer procedures. The values of these parameters may be set differently between network and UE.

7.3.3 Illustration of network and UE procedures

< *Editor's note: The contents of this subclause have been taken from Volume 3 figure 3.2.6-17.* >

Figure 6 illustrates the scheme for the case where transmission of downlink DPDCH is resumed.

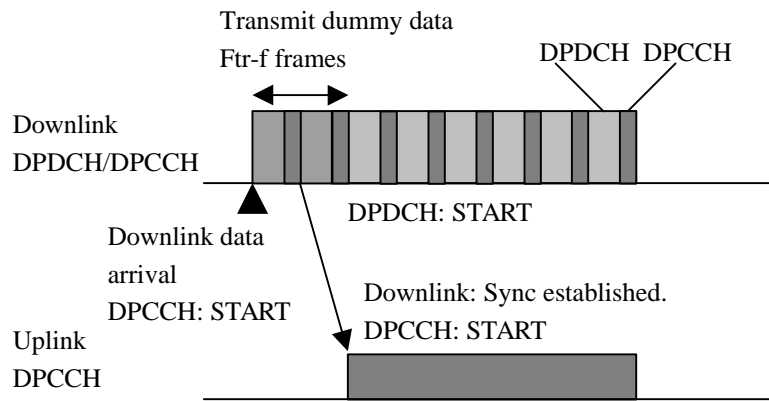

Figure 6: Transmission resumption of downlink DPDCH

Figure 7 illustrates the scheme for the case where transmission of uplink DPDCH is resumed.

Figure 7: Transmission resumption of downlink DPDCH

8 Feedback mode transmit diversity

< Editor's note: The contents of this clause are left out until the TX diversity issue is settled. >

9 Reverse link synchronous transmission

< Editor's note: This clause is only to be found in ARIB Volume 3. Some more discussion on this technique is probably needed, and for now the original text is kept. The physical layer procedures of RSTS needs to be identified and further refined and described in this clause. >

9.1 General

Reverse Link Synchronous Transmission (RSTS) can reduce reverse link intra-cell interference by means of making a BTS receive orthogonalized signals from MSs in the cell. To orthogonalize receiving signals from MSs,

- the same scrambling code is allocated to all dedicated physical channels in the cell,
- different orthogonal spreading codes are allocated to all dedicated physical channels across all MSs in the cell, and

- the signal arrival time of each MS is adjusted.

The modulation scheme according to RSTS is described in <update 3.2.4.2.1.2.2>. The timing control procedures are described later in this section. RSTS is an alternative technology applicable for low mobility terminals. A system mainly accommodating low mobility terminals may adopt the RSTS.

The transmission time control is carried out by two steps. The first step is initial synchronization and the second is tracking.

- 1) Initial synchronization: Adjust transmission time through the initial timing control message over FACH
- 2) Tracking Process (Closed Loop Timing control): Adjust the transmission time through the Time Alignment Bit (TAB) over DTCH.

9.2 Initial synchronisation

- When the BTS received signal from MS over RACH, BTS measures the difference in time between the received timing and the reference time.
- The message for initial synchronization is delivered to MS via FACH.
- MS adjust its transmission time according to the message (the maximum amount of adjustments corresponds to the round trip delay of a cell).
- When the difference in time of initial measurement in the first step is not big, it is possible to skip these initial synchronization processes.

9.3 Tracking process

- BTS periodically compares the difference between the reference time and received signal timing from MS.
- When the received timing is earlier than the reference time, Time Alignment Bit (TAB) = "0". When this is later than the reference time, TAB = "1".
- Since the timing control is carried out at much lower rate than TPC, TAB replaces the TPC bit every timing control period 20 msec. (In the exemplary embodiment, the timing control period equals to the frame length or multiples of it. In case of the example of timing control every frame, the first TPC bit of each frame is replaced by TAB)
- At the MS, soft decision on the TAB shall be performed, and when it is judged as "0", the transmission time shall be delayed by 1/4 (or 1/8) chip, whereas if it is judged as "1", the transmission time shall be advanced by 1/4 (or 1/8) chip.

9.4 Reference time

The reference time is set up at the starting point of forward-link frame plus the median value between minimum and maximum round trip delay within a cell. < Editor's note: How can one take the median of two values? >

Annex A (informative): Other procedures

A.1 Paging procedure

< Editor's note: If it is decided to keep this clause, the network operation should be moved to S1.11, and the annex could be renamed paging detection and possibly also moved to S1.11. >

A.1.1 Network operation

Every UE belongs to one group. When there exists a paging message for the UE, the paging message is transmitted on the PCH in the MUI-parts belonging to the UE's group. The paging message includes the mobile station identification number of the UE for which the paging message was intended. When a MUI is transmitted, the corresponding PI1 and PI2 fields are also transmitted.

The exact behaviour of the network is described as:

For the PCH of the group which does not have a paging message:

- The network shall transmit the two PI parts (PI1 and PI2) in the PCH as “all 0”.
- The MUI part shall not be transmitted.

For the PCH of the group which have a paging message:

- The network shall transmit the two PI parts (PI1 and PI2) in the PCH as “all 1”.
- The MUI part shall be transmitted within the same PCH.

A.1.2 UE operation

The idea behind the detection of paging messages is to open the receiver to detect one of or both the paging indicators (PI1 and PI2), and if they indicate a paging message for the group the UE belongs to, the actual paging information part (MUI) is received. When the MUI part is received, the existence of a paging message for the UE is determined from the information included in the MUI part.

The UE operation for detection of paging information in group n is shown in Figure 8. $PI1_n$, $PI2_n$, and MUI_n are the PCH components belong to group n .

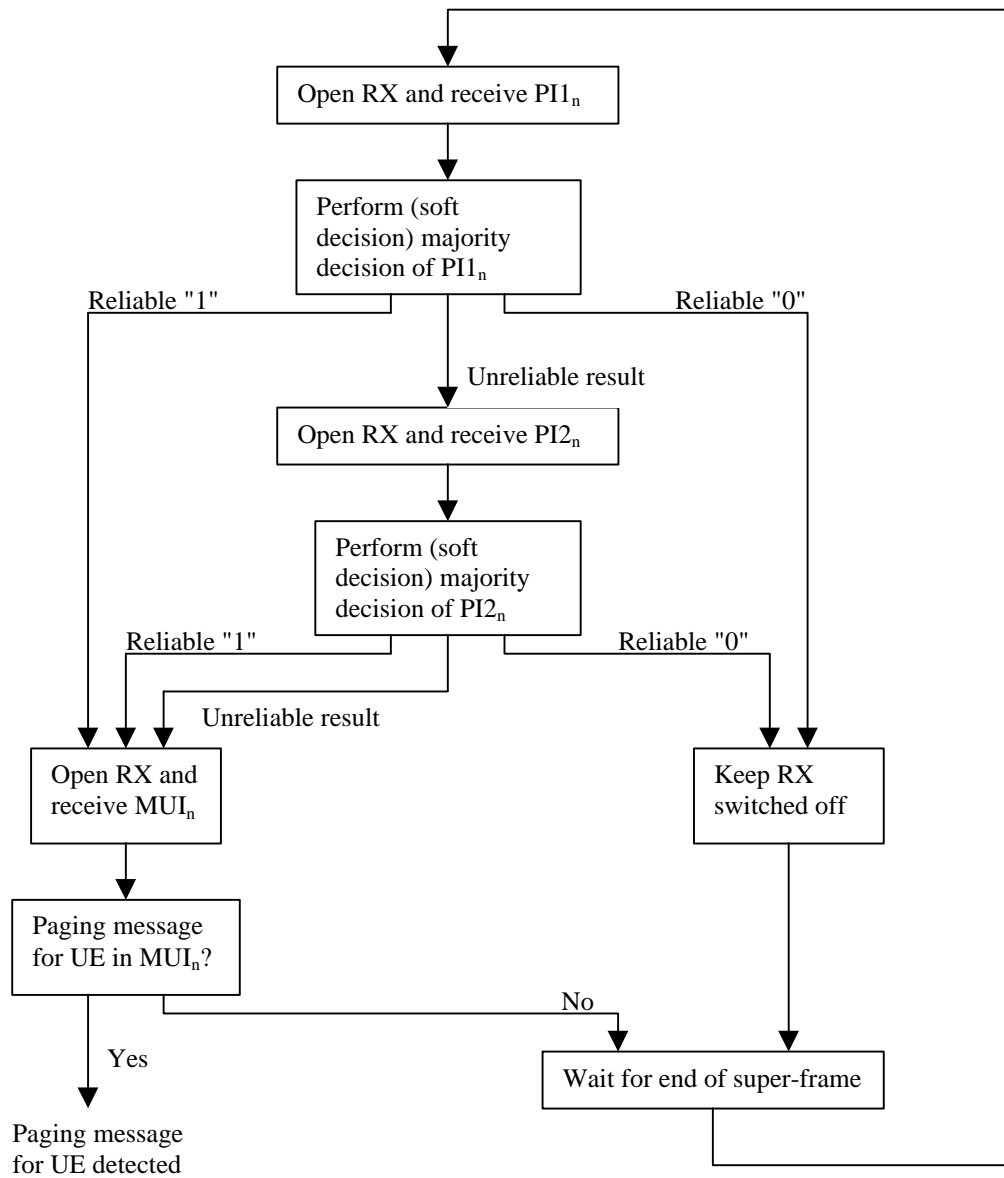

Figure 8: Detection of paging messages.
