 Release 00

Reason for change:

The current TFCI coding is not optimized in terms of minimum Hamming distance. This contribution changes the order of TFCI basis and proposes the optimized TFCI coding in FDD, which maximizes the minimum Hamming distance.

4.3.3 Coding of Transport-Format-Combination Indicator (TFCI)

The TFCI bits are encoded using a (32, 10) sub-code of the second order Reed-Muller code. The coding procedure is as shown in figure 10.

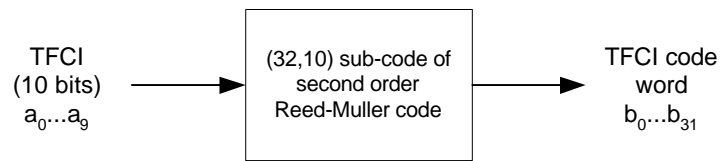

Figure 10: Channel coding of TFCI bits

If the TFCI consist of less than 10 bits, it is padded with zeros to 10 bits, by setting the most significant bits to zero. The length of the TFCI code word is 32 bits.

The code words of the (32,10) sub-code of second order Reed-Muller code are linear combination of 10 basis sequences. The basis sequences are as in the following table 7.

For TFCI information bits $a_0, a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9$ (a_0 is LSB and a_9 is MSB), the output code word bits b_i are given by:

$$b_i = \sum_{n=0}^9 (a_n \times M_{i,n}) \text{ mod } 2$$

where $i=0 \dots 31$.

The output bits are denoted by $b_k, k = 0, 1, 2, \dots, 31$.

In downlink, when the SF < 128 the encoded TFCI code words are repeated yielding 8 encoded TFCI bits per slot in normal mode and 16 encoded TFCI bits per slot in compressed mode. Mapping of repeated bits to slots is explained in section 4.3.5.

4.3.4 Operation of Transport-Format-Combination Indicator (TFCI) in Split Mode

In the case of DCH in Split Mode, the UTRAN shall operate with as follows:

- If one of the links is associated with a DSCH, the TFCI code word may be split in such a way that the code word relevant for TFCI activity indication is not transmitted from every cell. The use of such a functionality shall be indicated by higher layer signalling.

The TFCI bits are encoded using a (16, 5) bi-orthogonal (or first order Reed-Muller) code. The coding procedure is as shown in figure 11.

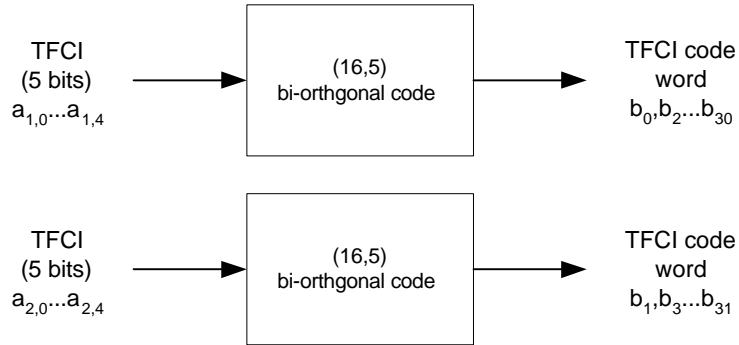

Figure 11: Channel coding of split mode TFCI bits

The code words of the (16,5) bi-orthogonal code are linear combinations of 5 basis sequences as defined in table 8 below.

Table 8: Basis sequences for (16,5) TFCI code

For TFCI information bits for DCH $a_{1,0}, a_{1,1}, a_{1,2}, a_{1,3}, a_{1,4}$ ($a_{1,0}$ is LSB and $a_{1,4}$ is MSB) and for DSCH $a_{2,0}, a_{2,1}, a_{2,2}, a_{2,3}, a_{2,4}$ ($a_{2,0}$ is LSB and $a_{2,4}$ is MSB), the output code word bits b_0, b_1, \dots, b_{31} , are given by:

$$b_{2i} = \sum_{n=0}^4 (a_{1,n} \times M_{i,n}) \bmod 2;$$

$$b_{2i+1} = \sum_{n=0}^4 (a_{2,n} \times M_{i,n}) \bmod 2$$

where $i=0\dots 15, j=0,1$.

The output bits are denoted by $b_k, k = 0, 1, 2, \dots, 31$.
