

TSG-RAN Working Group1 meeting #11

TSGR1#11(00)358

San Diego, CA, U.S.A., February 29 – March 3, 2000

**Agenda Item** : AH04 + AH08  
**Source** : Nortel Networks  
**Title** : Downlink Compressed Mode by Puncturing, update  
**Document for** : Decision

---

## 1. Introduction

This CR It provides a solution for downlink compressed mode by puncturing. It is an update of CR 25.212-042r2, presented in Tdoc R1-00174 at the RAN1 meeting #10. This update includes remarks from several companies received during the RAN1#10 meeting, and up to now.

Detailed explanations of the method can be found in Tdocs R1-00172 and R1-00173.

The modifications compared to CR 25.212-042r2 are listed thereafter, section by section.

### 4.2 Update downlink multiplexing chain notations

#### 4.2.5 First Interleaver:

- Addition of a subsection (4.5.2.1) explaining the insertion of bits p in the sequence to be input in first interleaver, in order not to mix relations of input and output bits with the description of the functionality itself
- Use  $X_i$  in the loop for insertion of the p-bits instead of  $R_i * C_i$
- Adapt the notations for the relations between input and output bits

#### 4.2.7 Rate matching:

- Clarify definition of  $N_{TGL}$  [k]

#### 4.2.7.2 Determination of rate matching parameters for downlink TrChs:

- Clarify that we use  $N'$  data instead of  $N_{data}$  as the number of bits available for the CCTRCH in case of compressed mode. This takes into account the fact that to keep the same number of TFCI bits, the number of bits available for data field is decreased.
- Add two subsections for calculation of the amount of rate matching for all modes, and amount of additional puncturing in case of compressed mode by puncturing
- Remove factor P in the calculation of the number of bits to puncture additionally for compressed mode, since  $N_{TGL}[k]$  contains bits for all Physical Channels

#### 4.2.9.1 First DTX insertion:

- Clarify that DTX bits insertion does not occupy the room for p-bits, created by additional puncturing in the rate matching step.

#### 4.2.9.2 Second DTX insertion:

- Clarify that DTX bits fill the whole data bits available for the CCTRCH, as in normal mode, since the p-bits are still there, so we do not need to reserve some space for the gap. The gap will be naturally created when p-bits are removed later in the description.

#### 4.2.10 Physical segmentation:

- Use a unified notation for compressed mode and normal mode, to fill each code with bits. In normal mode all bits of the input flow are taken, in compressed mode by puncturing only the bits not with value p are taken. This way p-

bits are removed in one step.

3GPP/SMG Meeting #10  
Beijing, China, 18 Jan-21 Jan 2000

Document **R1-00**

e.g. for 3GPP use the format TP-99xxx  
or for SMG, use the format P-99-xxx

## 4.2 Transport-channel coding/multiplexing

Data arrives to the coding/multiplexing unit in form of transport block sets once every transmission time interval. The transmission time interval is transport-channel specific from the set {10 ms, 20 ms, 40 ms, 80 ms}.

The following coding/multiplexing steps can be identified:

- Add CRC to each transport block (see section 4.2.1)
- Transport block concatenation and code block segmentation (see section 4.2.2)
- Channel coding (see section 4.2.3)
- Rate matching (see section 4.2.7)
- Insertion of discontinuous transmission (DTX) indication bits (see section 4.2.9)
- Interleaving (two steps, see sections 4.2.4 and 4.2.11)
- Radio frame segmentation (see section 4.2.6)
- Multiplexing of transport channels (see section 4.2.8)
- Physical channel segmentation (see section 4.2.10)
- Mapping to physical channels (see section 4.2.12)

The coding/multiplexing steps for uplink and downlink are shown in figure 1 and figure 2 respectively.

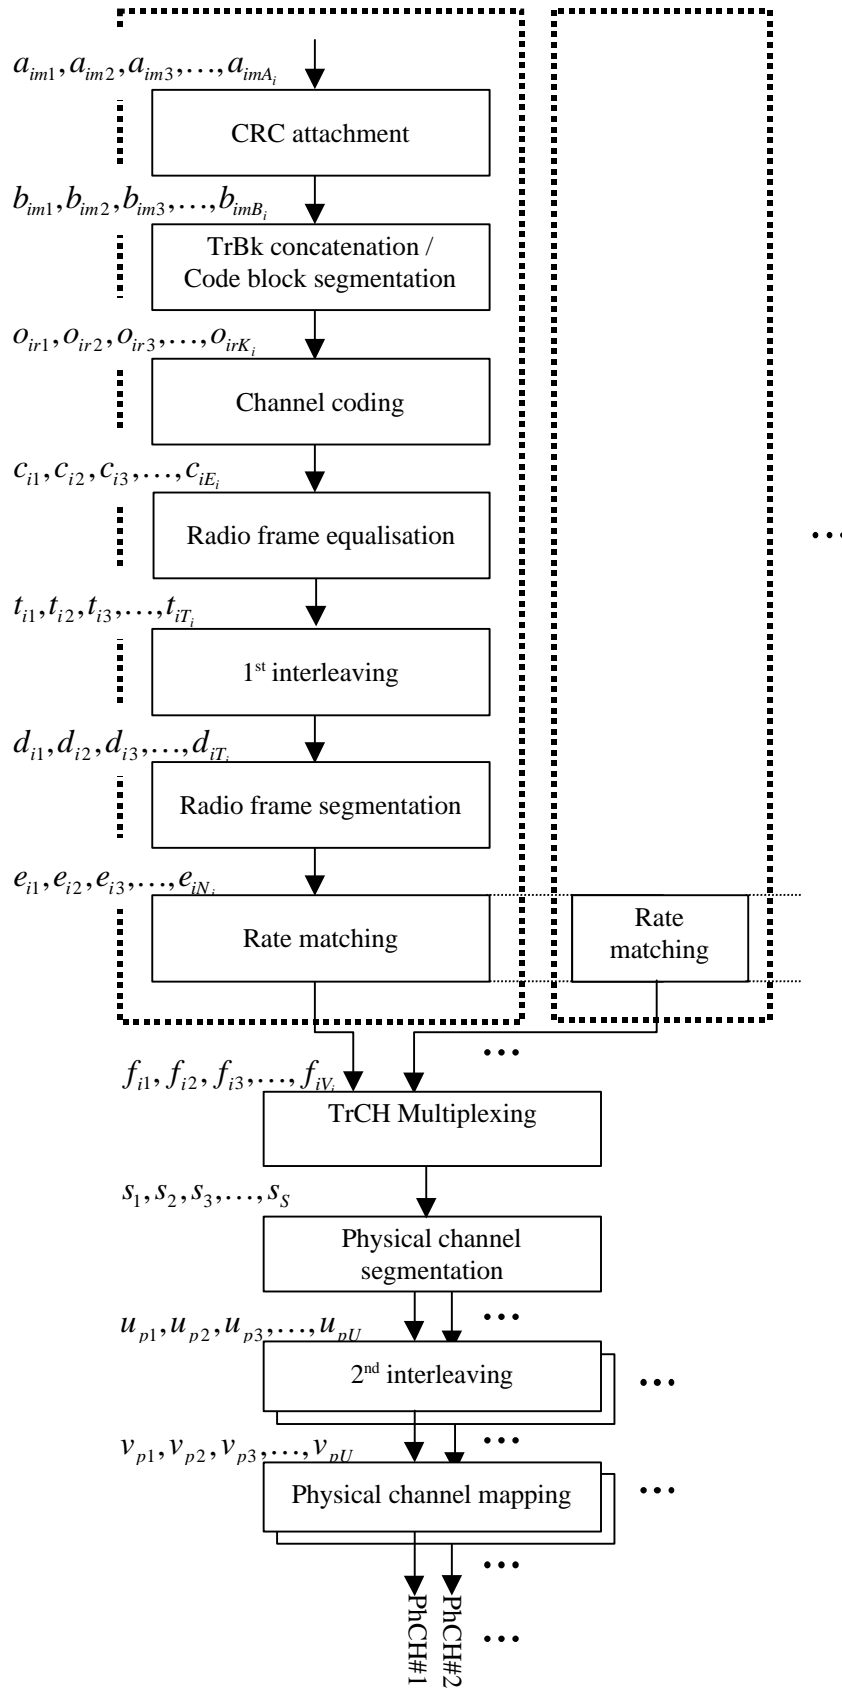

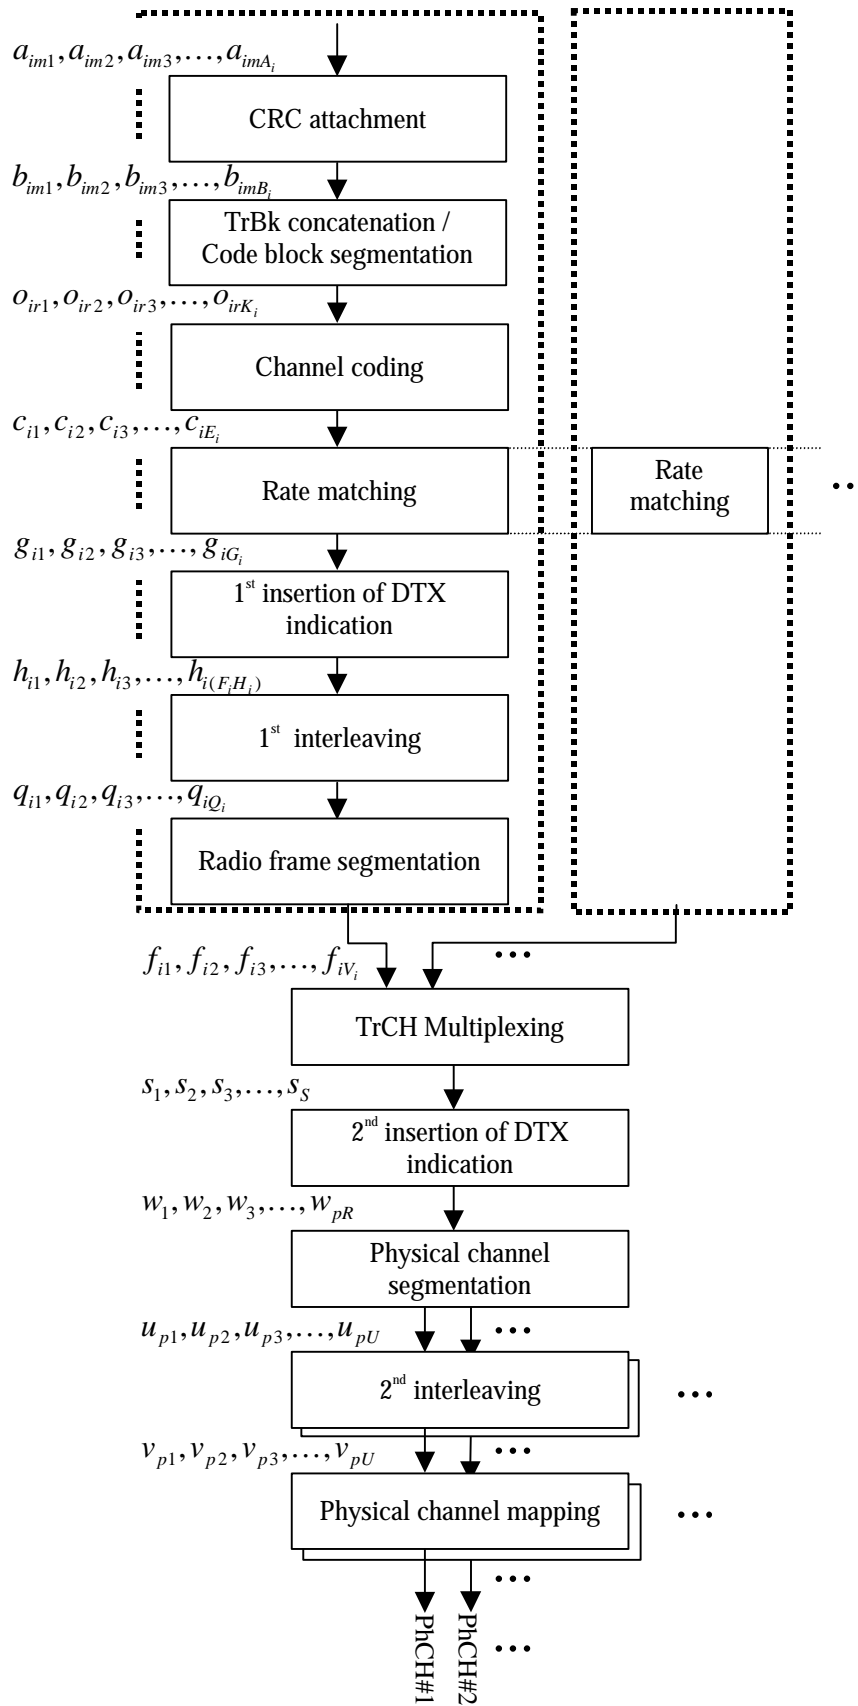

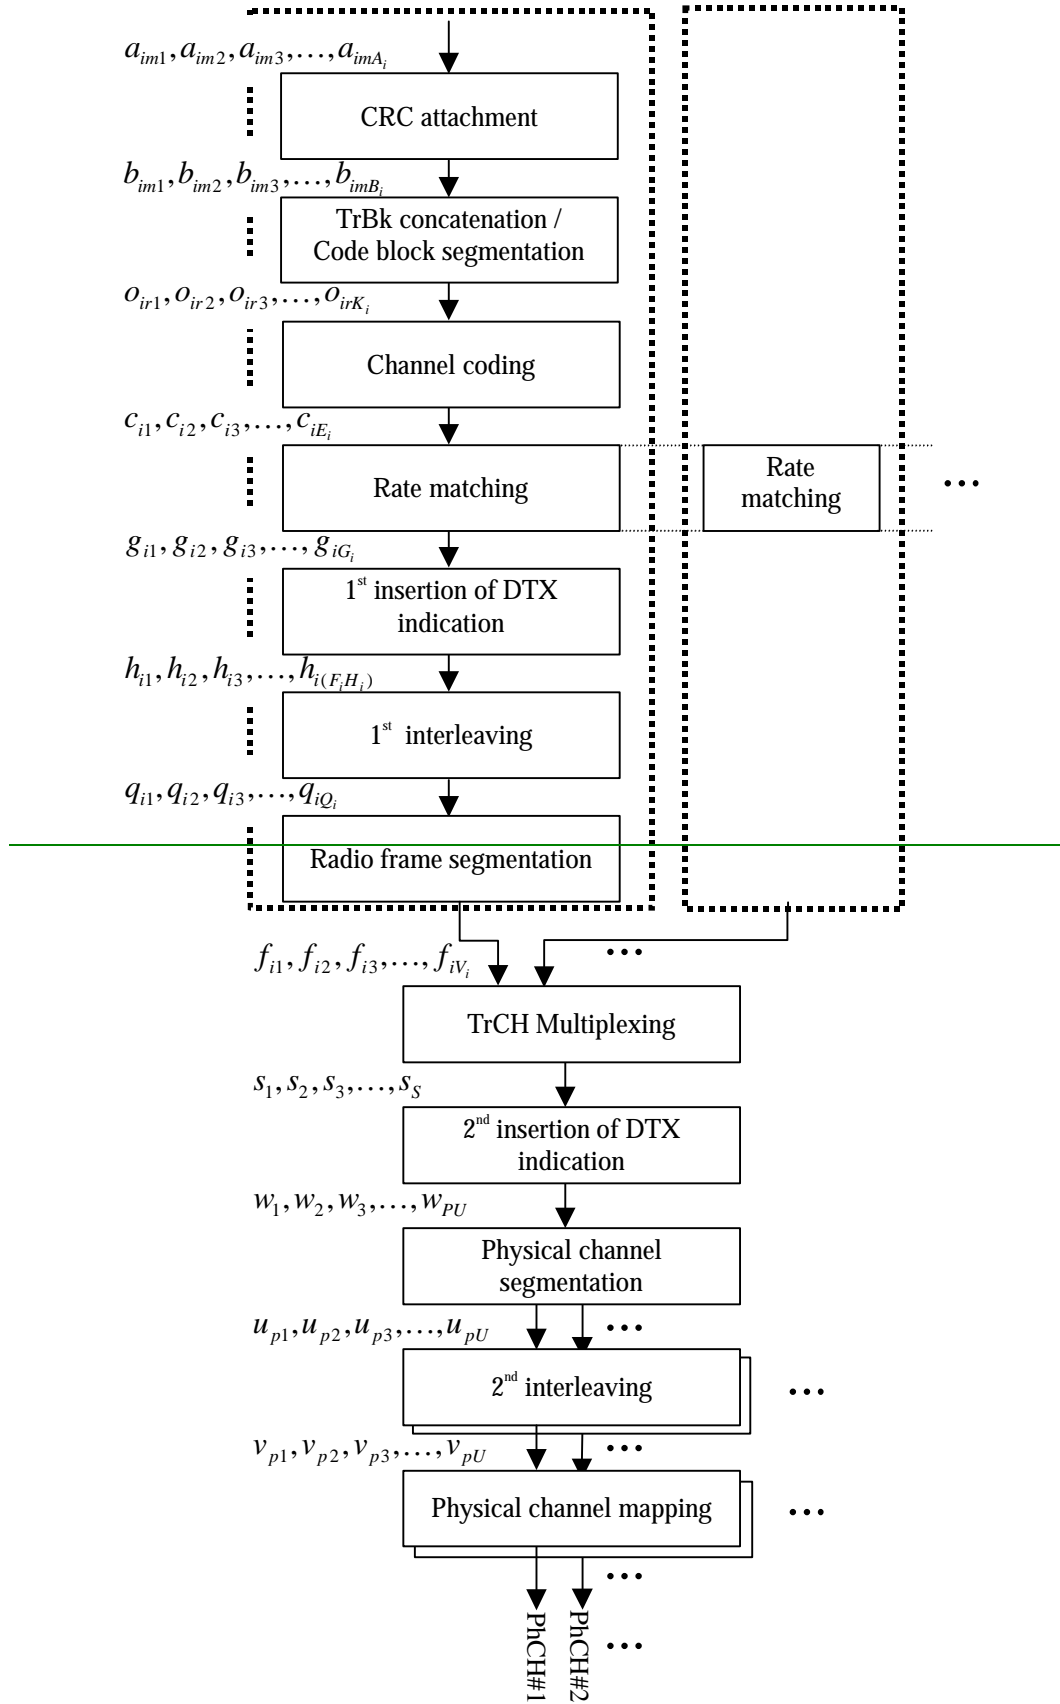

Figure 1: Transport channel multiplexing structure for uplink

**Figure 2: Transport channel multiplexing structure for downlink**

The single output data stream from the TrCH multiplexing is denoted *Coded Composite Transport Channel (CCTrCH)*. A CCTrCH can be mapped to one or several physical channels.

## 4.2.5 1<sup>st</sup> interleaving

In Compressed Mode by puncturing, bits marked with a fourth value on top of {0, 1,  $\delta$ } and noted p, are introduced in the radio frames to be compressed, in positions corresponding to the first bits of the radio frames. They will be removed in a later stage of the multiplexing chain to create the actual gap. Additional puncturing has been performed in the rate matching step, over the TTI containing the compressed radio frame, to create room for these p-bits. The following section describes this feature.

### 4.2.5.1 Insertion of marked bits in the sequence to be input in first interleaver

In other modes than compressed mode by puncturing,  $x_{ik} = z_{ik}$  and  $X_i = Z_i$ .

In compressed mode by puncturing, sequence  $x_{i,k}$  which will be input to first interleaver is built from bits  $z_{i,k}$ ,  $k=1, \dots, Z_i$ , plus  $\lfloor DN_{cm,i,max}^{TTI} \rfloor$  bits marked p if fixed positions are used, and  $X_i = Z_i + \lfloor DN_{cm,i,max}^{TTI} \rfloor$ , and  $x_{i,k}$  is built from bits  $z_{i,k}$ ,  $k=1, \dots, Z_i$ , plus  $\lfloor DN_{cm,il}^{TTI} \rfloor$  bits marked p if flexible positions are used, and  $X_i = Z_i + \lfloor DN_{cm,il}^{TTI} \rfloor$ , as is described thereafter.

$DN_{cm,i,max}^{TTI}$  and  $DN_{cm,il}^{TTI}$  are defined in the Rate Matching section 4.2.7

$P_{Fi}[x]$  defines the inter column permutation function for a TTI of length  $F_i * 10ms$ , as defined in Table 3 above.  $P_{Fi}[x]$  is the Bit Reversal function of x on  $\log_2(F_i)$  bits.

Note:

- $C[x]$ ,  $x=0$  to  $F_i - 1$ , the number of bits p which have to be inserted in each of the  $F_i$  segments of the TTI, i.e. in each column of the first interleaver.  $C[x]$  is equal to  $\lfloor \Delta N_{cm,i,max}[x] \rfloor$  for x equal 0 to  $F_i - 1$  if fixed positions are used.  $C[x]$  is equal to  $\lfloor \Delta N_{cm,i}[x] \rfloor$  for x equal 0 to  $F_i - 1$  if flexible positions are used. Both are noted  $\lfloor \Delta N_{cm,i}[x] \rfloor$  in the following initialisation step.
- $cbi[x]$ ,  $x=0$  to  $F_i - 1$ , the counter of the number of bits p inserted in each of the  $F_i$  segments of the TTI, i.e. in each column of the first interleaver.

col = 0

while col <  $F_i$  do

     $C[col] = \lfloor \Delta N_{cm,i}[col] \rfloor$  -- initialisation of number of bits p to be inserted in each of the  $F_i$  segments of the TTI

     $cbi[col] = 0$  -- initialisation of counter of number of bits p inserted in each of the  $F_i$  segments of the TTI

end do

n = 0, m = 0

while n <  $X_i$  do

    col = n mod  $F_i$

    if  $cbi[col] < C[P_{Fi}(col)]$  do

         $x_{i,n} = p$  -- insert one p bit

         $cbi[col] = cbi[col] + 1$  -- update counter of number of bits p inserted

    else -- no more p bit to insert in this segment

         $x_{i,n} = z_{i,m}$

        m = m + 1

    endif

n = n + 1

end do

**4.2.5.2 1<sup>st</sup> interleaver operation**

The 1<sup>st</sup> interleaving is a block interleaver with inter-column permutations. The input bit sequence to the 1<sup>st</sup> interleaver is denoted by  $x_{i1}, x_{i2}, x_{i3}, \dots, x_{iX_i}$ , where  $i$  is TrCH number and  $X_i$  the number of bits (at this stage  $X_i$  is assumed and guaranteed to be an integer multiple of TTI). The output bit sequence is derived as follows:

- (1) Select the number of columns  $C_I$  from table 3.
- (2) Determine the number of rows  $R_I$  defined as

$$R_I = X_i / C_I$$

- (3) Write the input bit sequence into the  $R_I \times C_I$  rectangular matrix row by row starting with bit  $x_{i,1}$  in the first column of the first row and ending with bit  $x_{i,(R_I C_I)}$  in column  $C_I$  of row  $R_I$ :

$$\begin{bmatrix} x_{i1} & x_{i2} & x_{i3} & \dots & x_{iC_I} \\ x_{i,(R_I+1)} & x_{i,(R_I C_I+2)} & x_{i,(R_I C_I+3)} & \dots & x_{i,(R_I C_I+ C_I)} \\ \vdots & \vdots & \vdots & \dots & \vdots \\ x_{i,(R_I-1)C_I+1} & x_{i,(R_I-1)C_I+2} & x_{i,(R_I-1)C_I+3} & \dots & x_{i,(R_I-1)C_I+ C_I} \end{bmatrix}$$

- (4) Perform the inter-column permutation based on the pattern  $\{P_j \mid j=0,1, \dots, C_I-1\}$  table 3, where  $P_1(j)$  denoted by  $i_k$ : After permutation of the columns, the bits are

$$\begin{bmatrix} y_{i1} & y_{i,(R_I+1)} & y_{i,(2R_I+1)} & \dots & y_{i,((C_I-1)R_I+1)} \\ y_{i2} & y_{i,(R_I+2)} & y_{i,(2R_I+2)} & \dots & y_{i,((C_I-1)R_I+2)} \\ \vdots & \vdots & \vdots & \dots & \vdots \\ y_{iR_I} & y_{i,(2R_I)} & y_{i,(3R_I)} & \dots & y_{i,(C_I R_I)} \end{bmatrix}$$

- (5) Read the output bit sequence  $y_{i1}, y_{i2}, y_{i3}, \dots, y_{i,(C_I R_I)}$  of the 1<sup>st</sup> interleaving column by column from the inter-column permuted  $R_I \times C_I$  matrix. Bit  $y_{i,1}$  corresponds to the first row of the first column and bit  $y_{i,(R_I C_I)}$  corresponds to row  $R_I$  of column  $C_I$ .

**Table 3**

TTI	Number of columns $C_I$	Inter-column permutation patterns
10 ms	1	{0}
20 ms	2	{0,1}
40 ms	4	{0,2,1,3}
80 ms	8	{0,4,2,6,1,5,3,7}

**4.2.5.34 Relation between input and output of 1<sup>st</sup> interleaving in uplink**

The bits input to the 1<sup>st</sup> interleaving are denoted by  $t_{i1}, t_{i2}, t_{i3}, \dots, t_{iT_i}$ , where  $i$  is the TrCH number and  $T_i$  the number of bits. Hence,  $t_{i,k} = t_{ik}$  and  $X_i = T_i$ .

The bits output from the 1<sup>st</sup> interleaving are denoted by  $d_{i1}, d_{i2}, d_{i3}, \dots, d_{iT_i}$ , and  $d_{ik} = y_{ik}$ .

#### 4.2.5.42 Relation between input and output of 1<sup>st</sup> interleaving in downlink

If fixed positions of the TrCHs in a radio frame is used then the bits input to the 1<sup>st</sup> interleaving are denoted by  $h_{i1}, h_{i2}, h_{i3}, \dots, h_{i(F_i H_i)}$ , where  $i$  is the TrCH number. Hence,  $x_{Z_{ik}} = h_{ik}$  and  $Z_i = F_i * H_i + DN_{cm, i, max}^{TTI}$  in compressed mode by puncturing, and  $x_{Z_i} = F_i H_i$  otherwise.

If flexible positions of the TrCHs in a radio frame is used then the bits input to the 1<sup>st</sup> interleaving are denoted by  $g_{i1}, g_{i2}, g_{i3}, \dots, g_{iG_i}$ , where  $i$  is the TrCH number. Hence,  $x_{Z_{ik}} = g_{ik}$  and  $x_{Z_i} = G_i$ .

The bits output from the 1<sup>st</sup> interleaving are denoted by  $q_{i1}, q_{i2}, q_{i3}, \dots, q_{iQ_i}$ , where  $i$  is the TrCH number and  $Q_i$  is the number of bits. Hence,  $q_{ik} = y_{ik}$ ,  $Q_i = F_i H_i$  if fixed positions are used, and  $Q_i = G_i$  if flexible positions are used.

## 4.2.7 Rate matching

Rate matching means that bits on a transport channel are repeated or punctured. Higher layers assign a rate-matching attribute for each transport channel. This attribute is semi-static and can only be changed through higher layer signalling. The rate-matching attribute is used when the number of bits to be repeated or punctured is calculated.

The number of bits on a transport channel can vary between different transmission time intervals. In the downlink the transmission is interrupted if the number of bits is lower than maximum. When the number of bits between different transmission time intervals in uplink is changed, bits are repeated or punctured to ensure that the total bit rate after TrCH multiplexing is identical to the total channel bit rate of the allocated dedicated physical channels.

If no bits are input to the rate matching for all TrCHs within a CCTrCH, the rate matching shall output no bits for all TrCHs within the CCTrCH and no uplink DPDCH will be selected in the case of uplink rate matching.

### Notation used in section 4.2.7 and subsections:

$N_{ij}$ : For uplink: Number of bits in a radio frame before rate matching on TrCH  $i$  with transport format combination  $j$ .

For downlink : An intermediate calculation variable (not an integer but a multiple of 1/8).

$N_{il}^{TTI}$  : Number of bits in a transmission time interval before rate matching on TrCH  $i$  with transport format  $l$ .  
Used in downlink only.

$\Delta N_{ij}$  : For uplink: If positive - number of bits that should be repeated in each radio frame on TrCH  $i$  with transport format combination  $j$ .

If negative - number of bits that should be punctured in each radio frame on TrCH  $i$  with transport format combination  $j$ .

For downlink : An intermediate calculation variable (not an integer but a multiple of 1/8).

$\Delta N_{il}^{TTI}$  : If positive - number of bits to be repeated in each transmission time interval on TrCH  $i$  with transport format  $j$ .

If negative - number of bits to be punctured in each transmission time interval on TrCH  $i$  with transport format  $j$ .

Used in downlink only.

$DN_{cm,ij}^{TTI}$ : Negative or null: number of bits to be removed in one Transmission Time Interval, to create the required gaps in the compressed radio frames of this TTI, in case of compressed mode by puncturing, for TrCh  $i$  with transport format  $j$ .

Used in downlink only.

$DN_{cm,ij}[k]$ ,  $k=0$  to  $F_i-1$ : Negative or null: number of bits, in each radio frame of the TTI corresponding to the gap for compressed mode in this radio frame, for TrCH  $i$  with transport format  $j$ . The value will be null for the un-compressed radio frames.

Used in downlink only.

$N_{TGL}[k]$ ,  $k=0$  to  $F_i-1$  : Positive or null: number of bits in each radio frame corresponding to the gap for compressed mode for the CCTrCh.

$RM_i$ : Semi-static rate matching attribute for transport channel  $i$ . Signalled from higher layers.

$PL$ : Puncturing limit for uplink. This value limits the amount of puncturing that can be applied in order to avoid multicode or to enable the use of a higher spreading factor. Signalled from higher layers.

$N_{data,j}$ : Total number of bits that are available for the CCTrCH in a radio frame with transport format combination  $j$ .

$I$ : Number of TrCHs in the CCTrCH.

- $Z_{ij}$ : Intermediate calculation variable.
- $F_i$ : Number of radio frames in the transmission time interval of TrCH  $i$ .
- $n_i$ : Radio frame number in the transmission time interval of TrCH  $i$  ( $0 \leq n_i < F_i$ ).
- $q$ : Average puncturing or repetition distance (normalised to only show the remaining rate matching on top of an integer number of repetitions). Used in uplink only.
- $I_F(n_i)$ : The inverse interleaving function of the 1<sup>st</sup> interleaver (note that the inverse interleaving function is identical to the interleaving function itself for the 1<sup>st</sup> interleaver). Used in uplink only.
- $S(n_i)$ : The shift of the puncturing or repetition pattern for radio frame  $n_i$ . Used in uplink only.
- $TF_i(j)$ : Transport format of TrCH  $i$  for the transport format combination  $j$ .
- $TFS(i)$ : The set of transport format indexes  $l$  for TrCH  $i$ .
- $TFCS$ : The set of transport format combination indexes  $j$ .
- $e_{ini}$ : Initial value of variable  $e$  in the rate matching pattern determination algorithm of section 4.2.7.5.
- $e_{plus}$ : Increment of variable  $e$  in the rate matching pattern determination algorithm of section 4.2.7.5.
- $e_{minus}$ : Decrement of variable  $e$  in the rate matching pattern determination algorithm of section 4.2.7.5.
- $b$ : Indicates systematic and parity bits
- $b=1$ : Systematic bit.  $X(t)$  in section 4.2.3.2.1.
- $b=2$ : 1<sup>st</sup> parity bit (from the upper Turbo constituent encoder).  $Y(t)$  in section 4.2.3.2.1.
- $b=3$ : 2<sup>nd</sup> parity bit (from the lower Turbo constituent encoder).  $Y'(t)$  in section 4.2.3.2.1.

The \* (star) notation is used to replace an index  $x$  when the indexed variable  $X_x$  does not depend on the index  $x$ . In the left wing of an assignment the meaning is that " $X_* = Y$ " is equivalent to "**for all  $x$  do  $X_x = Y$** ". In the right wing of an assignment, the meaning is that " $Y = X_*$ " is equivalent to "**take any  $x$  and do  $Y = X_x$** ".

The following relations, defined for all TFC  $j$ , are used when calculating the rate matching parameters:

$$Z_{0,j} = 0$$

$$Z_{ij} = \left[ \frac{\sum_{m=1}^i RM_m \cdot N_{mj}}{\sum_{m=1}^I RM_m \cdot N_{mj}} \cdot N_{data,j} \right] \text{ for all } i = 1 .. I \quad (1)$$

$$\Delta N_{ij} = Z_{ij} - Z_{i-1,j} - N_{ij} \quad \text{for all } i = 1 .. I$$

#### 4.2.7.1 Determination of rate matching parameters in uplink

##### 4.2.7.1.1 Determination of SF and number of PhCHs needed

In uplink, puncturing can be applied to match the CCTrCH bit rate to the PhCH bit rate. The bit rate of the PhCH(s) is limited by the UE capability and restrictions imposed by UTRAN, through limitations on the PhCH spreading factor. The maximum amount of puncturing that can be applied is signalled from higher layers and denoted by  $PL$ . The number of available bits in the radio frames for all possible spreading factors is given in [2]. Denote these values by  $N_{256}$ ,  $N_{128}$ ,  $N_{64}$ ,  $N_{32}$ ,  $N_{16}$ ,  $N_8$ , and  $N_4$ , where the index refers to the spreading factor. The possible values of  $N_{data}$  then are  $\{N_{256}, N_{128}, N_{64}, N_{32}, N_{16}, N_8, N_4, 2N_4, 3N_4, 4N_4, 5N_4, 6N_4\}$ . Depending on the UE capability and the restrictions from UTRAN, the allowed set of  $N_{data}$ , denoted SET0, can be a subset of  $\{N_{256}, N_{128}, N_{64}, N_{32}, N_{16}, N_8, N_4, 2N_4, 3N_4, 4N_4, 5N_4, 6N_4\}$ .  $N_{data,j}$  for the transport format combination  $j$  is determined by executing the following algorithm:

$$\text{SET1} = \{ N_{data} \text{ in SET0 such that } N_{data} - \sum_{x=1}^I \frac{RM_x}{\min_{1 \leq y \leq I} \{RM_y\}} \cdot N_{x,j} \text{ is non negative} \}$$

If SET1 is not empty and the smallest element of SET1 requires just one PhCH then

$$N_{data,j} = \min \text{ SET1}$$

else

$$\text{SET2} = \{ N_{data} \text{ in SET0 such that } N_{data} - PL \cdot \sum_{x=1}^I \frac{RM_x}{\min_{1 \leq y \leq I} \{RM_y\}} \cdot N_{x,j} \text{ is non negative} \}$$

Sort SET2 in ascending order

$$N_{data} = \min \text{ SET2}$$

While  $N_{data}$  is not the max of SET2 and the follower of  $N_{data}$  requires no additional PhCH do

$$N_{data} = \text{follower of } N_{data} \text{ in SET2}$$

End while

$$N_{data,j} = N_{data}$$

End if

#### 4.2.7.1.2 Determination of parameters needed for calculating the rate matching pattern

The number of bits to be repeated or punctured,  $DN_{ij}$ , within one radio frame for each TrCH  $i$  is calculated with equation 1 for all possible transport format combinations  $j$  and selected every radio frame.  $N_{data,j}$  is given from section 4.2.7.1.1.

In compressed mode  $N_{data,j}$  is replaced by  $N_{data,j}^{cm}$  in Equation 1.  $N_{data,j}^{cm}$  is given from the following relation:

$$N_{data,j}^{cm} = 2N_{data,j} - 2N_{TGL}, \text{ for compressed mode by spreading factor reduction}$$

$$N_{data,j}^{cm} = N_{data,j} - N_{TGL}, \text{ for compressed mode by higher layer scheduling}$$

$$N_{TGL} = \begin{cases} \frac{TGL}{15} N_{data,j}, & \text{if } N_{first} + TGL \leq 15 \\ \frac{15 - N_{first}}{15} N_{data,j}, & \text{in first frame if } N_{first} + TGL > 15 \\ \frac{TGL - (15 - N_{first})}{15} N_{data,j}, & \text{in second frame if } N_{first} + TGL > 15 \end{cases}$$

$N_{first}$  and  $TGL$  are defined in section 4.4.

If  $DN_{ij} = 0$  then the output data of the rate matching is the same as the input data and the rate matching algorithm of section 4.2.7.5 does not need to be executed.

If  $DN_{ij} \neq 0$  the parameters listed in sections 4.2.7.1.2.1 and 4.2.7.1.2.2 shall be used for determining  $e_{ini}$ ,  $e_{plus}$ , and  $e_{minus}$  (regardless if the radio frame is compressed or not).

##### 4.2.7.1.2.1 Uncoded and convolutionally encoded TrCHs

$R = DN_{ij} \bmod N_{ij}$  -- note: in this context  $DN_{ij} \bmod N_{ij}$  is in the range of 0 to  $N_{ij}-1$  i.e.  $-1 \bmod 10 = 9$ .

if  $R \neq 0$  and  $2R \leq N_{ij}$

then  $q = \lceil N_{ij} / R \rceil$

else

$q = \lceil N_{ij} / (R - N_{ij}) \rceil$

endif

-- note:  $q$  is a signed quantity.

if  $q$  is even

then  $q' = q + \text{gcd}(|q|, F_i)/F_i$  -- where  $\text{gcd}(|q|, F_i)$  means greatest common divisor of  $|q|$  and  $F_i$

-- note that  $q'$  is not an integer, but a multiple of  $1/8$

else

$q' = q$

endif

for  $x = 0$  to  $F_i - 1$

$S(I_F(|x \cdot q'| \bmod F_i)) = (|x \cdot q'| \text{ div } F_i)$

end for

$\Delta N_i = \Delta N_{ij}$

$a = 2$

For each radio frame, the rate-matching pattern is calculated with the algorithm in section 4.2.7.5, where :

$X_i = N_{ij}$ , and

$e_{\text{mi}} = (a \cdot S(n_i) \cdot |\Delta N_i| + 1) \bmod (a \cdot N_{ij})$ .

$e_{\text{plus}} = a \cdot N_{ij}$

$e_{\text{minus}} = a \cdot |\Delta N_i|$

puncturing for  $\Delta N < 0$ , repetition otherwise.

#### 4.2.7.1.2.2 Turbo encoded TrCHs

If repetition is to be performed on turbo encoded TrCHs, i.e.  $\Delta N_{i,j} > 0$ , the parameters in section 4.2.7.1.2.1 are used.

If puncturing is to be performed, the parameters below shall be used. Index  $b$  is used to indicate systematic ( $b=1$ ), 1<sup>st</sup> parity ( $b=2$ ), and 2<sup>nd</sup> parity bit ( $b=3$ ).

$a=2$  when  $b=2$

$a=1$  when  $b=3$

$$\Delta N_i = \begin{cases} \lfloor \Delta N_{i,j} / 2 \rfloor, & b = 2 \\ \lfloor \Delta N_{i,j} / 2 \rfloor, & b = 3 \end{cases}$$

$X_i = \lfloor N_{ij} / 3 \rfloor$ ,

$q = \lfloor X_i / |\Delta N_i| \rfloor$

if( $q \leq 2$ )

for  $x=0$  to  $F_i - 1$

$S[I_F((3x+b-1) \bmod F_i)] = x \bmod 2$ ;

```

end for
else
if q is even
then  $q' = q - gcd(q, F_i) / F_i$  -- where  $gcd(q, F_i)$  means greatest common divisor of  $q$  and  $F_i$ 
-- note that  $q'$  is not an integer, but a multiple of 1/8
else  $q' = q$ 
endif
for  $x=0$  to  $F_i - 1$ 
 $r = \lceil x * q' \rceil \bmod F_i$ ;
 $S[\lfloor F_i[(3r+b-1) \bmod F_i] \rfloor] = \lceil x * q' \rceil \text{ div } F_i$ ;
endfor
endif

```

For each radio frame, the rate-matching pattern is calculated with the algorithm in section 4.2.7.5, where:

$X_i$  is as above,

$e_{ini} = (a \cdot S(n_i) \cdot |\Delta N_i| + X_i) \bmod (a \cdot X_i)$ , if  $e_{ini} = 0$  then  $e_{ini} = a \cdot X_i$ .

$e_{plus} = a \cdot X_i$

$e_{minus} = a \cdot |\Delta N_i|$

#### 4.2.7.2 Determination of rate matching parameters in downlink

For downlink  $N_{data,j}$  does not depend on the transport format combination  $j$ .  $N_{data,*}$  is given by the channelization code(s) assigned by higher layers.

In the following, the amount of puncturing or repetition for the TTI, as determined by the rate matching parameters provided by higher layers is calculated. It is noted  $DN_{max}$  for fixed positions, and noted  $DN_{il}^{TTI}$  for flexible positions.

In case of compressed mode, for these calculations,  $N'_{data,*}$  is used instead of  $N_{data,*}$ .

where  $N'_{data,*} = P(15N'_{data1} + 15N'_{data2}) \cdot N'_{data1}$  and  $N'_{data2}$  are the number of bits in the data fields of the slot format used for the current compressed mode, i.e. slot format A or B as defined in [2] corresponding to the Spreading Factor and the number of transmitted slots in use.

Additional calculations for compressed mode by puncturing:

For compressed mode by puncturing, in TTIs where some compressed radio frames occur, the puncturing is increased or the repetition is decreased compared to what is calculated according to the rate matching parameters provided by higher layers. This allows to create room for later insertion of marked bits, noted p-bits, which will identify the positions of the gaps in the compressed radio frames.

The amount of additional puncturing corresponds to the number of bits to create the gap in the TTI for TrCh<sub>i</sub>. It is calculated in addition to the amount of rate matching indicated by higher layers. It is noted  $DN_{cm,i,max}^{TTI}$  for fixed position, and noted  $DN_{cm,il}^{TTI}$  for flexible positions.

To obtain the resulting rate matching to be performed on the TTI,  $DN_{max}$  and  $DN_{cm,i,max}^{TTI}$  are added in case of fixed positions,  $DN_{il}^{TTI}$  and  $DN_{cm,il}^{TTI}$  are added in case of flexible positions. If the result is null, i.e. the amount of repetition matches exactly the amount of additional puncturing needed, then no rate matching is necessary.

The number of bits corresponding to the gap for TrCh  $i$ , in each radio frame of its TTI is calculated using the number of bits to remove on each Physical Channel  $N_{TGL}[k]$ , where  $k$  is the radio frame number in the TTI.

For each radio frame  $k$  of the TTI,  $N_{TGL}[k]$  is given by the relation:

$$N_{TGL} = \begin{cases} \frac{TGL}{15} N'_{data,*}, & \text{if } N_{first} + TGL \leq 15 \\ \frac{15 - N_{first}}{15} N'_{data,*}, & \text{in first radio frame of the gap if } N_{first} + TGL > 15 \\ \frac{TGL - (15 - N_{first})}{15} N'_{data,*}, & \text{in second radio frame of the gap if } N_{first} + TGL > 15 \end{cases}$$

$N_{first}$  and  $TGL$  are defined in section 4.4.

Note that  $N_{TGL}[k] = 0$  if radio frame  $k$  is not compressed.

#### 4.2.7.2.1 Determination of rate matching parameters for fixed positions of TrCHs

##### 4.2.7.2.1.1 Calculation of $DN_{max}$ for normal mode and all methods of compressed mode

First an intermediate calculation variable  $N_{i,*}$  is calculated for all transport channels  $i$  by the following formula:

$$N_{i,*} = \frac{1}{F_i} \cdot \max_{l \in TFS(i)} N_{i,l}^{TTI}$$

The computation of the  $\Delta N_{i,l}^{TTI}$  parameters is then performed in for all TrCH  $i$  and all TF  $l$  by the following formula, where  $\Delta N_{i,*}$  is derived from  $N_{i,*}$  by the formula given at section 4.2.7:

$$\Delta N_{max} = F_i \cdot \Delta N_{i,*}$$

In other modes than compressed mode by puncturing, If  $\Delta N_{max} = 0$  then, for TrCH  $i$ , the output data of the rate matching is the same as the input data and the rate matching algorithm of section 4.2.7.5 does not need to be executed. In this case we have :

$$\forall l \in TFS(i) \Delta N_{i,l}^{TTI} = 0$$

If  $\Delta N_{max} \neq 0$  the parameters listed in sections 4.2.7.2.1.1 and 4.2.7.2.1.2 shall be used for determining  $e_{mi}$ ,  $e_{plus}$ , and  $e_{minus}$ .

##### 4.2.7.2.1.2 Additional calculation of $DN_{cm,i,max}^{TTI}$ for compressed mode by puncturing:

Let  $|DN_{cm,i,max}[k]|$  be the number of bits to eliminate on TrCh  $i$  to create the gap for compressed mode, in each radio frame  $k$  of the TTI, calculated for the Transport Format Combination of TrCh  $i$ , in which the number of bits of TrCh  $i$  is at its maximum.

$DN_{cm,i,max}[k]$  is calculated for each radio frame  $k$  of the TTI in the following way.

Intermediate variables  $Z_i$  for  $i = 1$  to  $I$  are calculated using the formula (1) in 4.2.7, by replacing  $N_{data,j}$  by  $N_{TGL}[k]$ .

Then  $DN_{cm,i,max}[k] = -(Z_i - Z_{i-1})$  for  $i = 1$  to  $I$

The total number of bits  $DN_{cm,i,max}^{TTI}$  corresponding to the gaps for compressed mode for TrCh  $i$  in the TTI is calculated as:

$$DN_{cm,i,max}^{TTI} = \sum_{k=0}^{F_i-1} DN_{cm,i,max}[k]$$

If  $DN_{max} \equiv \lfloor DN_{cm,i,max}^{TTI} \rfloor$ , then, for TrCH  $i$ , the output data of the rate matching is the same as the input data and the rate matching algorithm of section 4.2.7.5 does not need to be executed. If  $DN_{max} \neq \lfloor DN_{cm,i,max}^{TTI} \rfloor$ , then, for TrCH  $i$ , the rate matching algorithm of section 4.2.7.5 needs to be executed.

#### 4.2.7.2.1.34 ———— Determination of rate matching parameters for Uncoded and convolutionally encoded TrCHs

$$\Delta N_i = \Delta N_{max}$$

For compressed mode by puncturing,  $DN_i$  is defined as:  $DN_i = DN_{max} + DN_{cm,i,max}^{TTI}$  instead of the previous relation.

$$a=2$$

$$N_{max} = \max_{l \in TFS(i)} N_{il}^{TTI}$$

For each transmission time interval of TrCH  $i$  with TF  $l$ , the rate-matching pattern is calculated with the algorithm in section 4.2.7.5. The following parameters are used as input:

$$X_i = N_{il}^{TTI}$$

$$e_{ini} = 1$$

$$e_{plus} = a \cdot N_{max}$$

$$e_{minus} = a \cdot |\Delta N_i|$$

Puncturing if  $\Delta N_i < 0$ , repetition otherwise. The values of  $\Delta N_{i,l}^{TTI}$  may be computed by counting repetitions or puncturing when the algorithm of section 4.2.7.5 is run.

#### 4.2.7.2.1.42\_ ———— Determination of rate matching parameters for Turbo encoded TrCHs

If repetition is to be performed on turbo encoded TrCHs, i.e.  $\Delta N_{max} > 0$ , the parameters in section 4.2.7.2.1.1 are used.

If puncturing is to be performed, the parameters below shall be used. Index  $b$  is used to indicate systematic ( $b=1$ ), 1<sup>st</sup> parity ( $b=2$ ), and 2<sup>nd</sup> parity bit ( $b=3$ ).

$$a=2 \text{ when } b=2$$

$$a=1 \text{ when } b=3$$

The bits indicated by  $b=1$  shall not be punctured.

$$\Delta N_i = \begin{cases} \lfloor \Delta N_{max}/2 \rfloor, & b=2 \\ \lceil \Delta N_{max}/2 \rceil, & b=3 \end{cases}$$

In Compressed Mode by puncturing, the following relations are used instead of the previous ones:

$$DN_i = \mathbf{\hat{e}} DN_{max}/2 \mathbf{\hat{u}} + \mathbf{\hat{e}} DN_{cm,i,max}^{TTI}/2 \mathbf{\hat{u}}, \quad b=2$$

$$DN_i = \mathbf{\hat{e}} DN_{max}/2 \mathbf{\hat{u}} + \mathbf{\check{e}} DN_{cm,i,max}^{TTI}/2 \mathbf{\hat{u}}, \quad b=3$$

$$N_{max} = \max_{l \in TFS(i)} (N_{il}^{TTI} / 3)$$

For each transmission time interval of TrCH  $i$  with TF  $l$ , the rate-matching pattern is calculated with the algorithm in section 4.2.7.5. The following parameters are used as input:

$$X_i = N_{il}^{TTI} / 3$$

$$e_{ini} = N_{max}$$

$$e_{plus} = a \cdot N_{max}$$

$$e_{minus} = a \cdot |\Delta N_i|$$

The values of  $\Delta N_{i,l}^{TTI}$  may be computed by counting repetitions or puncturing when the algorithm of section 4.2.7.5 is run.

#### 4.2.7.2.2 Determination of rate matching parameters for flexible positions of TrCHs

##### 4.2.7.2.2.1 Calculation of $\Delta N_{i,l}^{TTI}$ for normal mode and all compressed mode methods

First an intermediate calculation variable  $N_{ij}$  is calculated for all transport channels  $i$  and all transport format combinations  $j$  by the following formula:

$$N_{i,j} = \frac{1}{F_i} \cdot N_{i,TF_i(j)}^{TTI}$$

Then rate matching ratios  $RF_i$  are calculated for each the transport channel  $i$  in order to minimise the number of DTX bits when the bit rate of the CCTrCH is maximum. The  $RF_i$  ratios are defined by the following formula:

$$RF_i = \frac{N_{data,*}}{\max_{j \in TFCS} \sum_{i=1} (RM_i \cdot N_{i,j})} \cdot RM_i$$

The computation of  $\Delta N_{i,l}^{TTI}$  parameters is then performed in two phases. In a first phase, tentative temporary values of  $\Delta N_{i,l}^{TTI}$  are computed, and in the second phase they are checked and corrected. The first phase, by use of the  $RF_i$  ratios, ensures that the number of DTX indication bits inserted is minimum when the CCTrCH bit rate is maximum, but it does not ensure that the maximum CCTrCH bit rate is not greater than  $N_{data,*}$  per 10ms. The latter condition is ensured through the checking and possible corrections carried out in the second phase.

At the end of the second phase, the latest value of  $\Delta N_{i,l}^{TTI}$  is the definitive value.

The first phase defines the tentative temporary  $\Delta N_{i,l}^{TTI}$  for all transport channel  $i$  and any of its transport format  $l$  by use of the following formula:

$$\Delta N_{i,l}^{TTI} = F_i \cdot \left[ \frac{RF_i \cdot N_{i,l}^{TTI}}{F_i} \right] - N_{i,l}^{TTI}$$

The second phase is defined by the following algorithm:

for all  $j$  in  $TFCS$  do -- for all TFC

$$D = \sum_{i=1}^{I} \frac{N_{i,TF_i(j)}^{TTI} + \Delta N_{i,TF_i(j)}^{TTI}}{F_i} \quad \text{-- CCTrCH bit rate (bits per 10ms) for TFC } l$$

if  $D > N_{data,*}$  then

for  $i = 1$  to  $I$  do -- for all TrCH

$$\Delta N = F_i \cdot \Delta N_{i,j} \quad \text{-- } \Delta N_{i,j} \text{ is derived from } N_{i,j} \text{ by the formula given at section 4.2.7.}$$

if  $\Delta N_{i,TF_i(j)}^{TTI} > \Delta N$  then

$$\Delta N_{i,TF_i(j)}^{TTI} = \Delta N$$

end-if

end-for

end-if

end-for

NOTE: The order in which the transport format combinations are checked does not change the final result.

For other modes than compressed mode by puncturing, if  $\Delta N_{i,l}^{TTI} = 0$  then, for TrCH  $i$  at TF  $l$ , the output data of the rate matching is the same as the input data and the rate matching algorithm of section 4.2.7.5 does not need to be executed.

If  $\Delta N_{i,l}^{TTI} \neq 0$  the parameters listed in sections 4.2.7.2.2.1 and 4.2.7.2.2.2 shall be used for determining  $e_{ini}$ ,  $e_{plus}$ , and  $e_{minus}$ .

#### 4.2.7.2.2.2 Additional calculation of $DN_{cm,il}^{TTI}$ for compressed mode by puncturing:

The number of bits for TrCh  $i$  corresponding to the gap for compressed mode in radio frame  $k$  of the TTI, noted  $|DN_{cm,il}[k]|$ , is calculated for each radio frame  $k$  of the TTI and for each TrCh of transport format combination  $l$ , as follows:

Intermediate variables  $Z_i$  for  $i = 1$  to  $I$  are calculated using the formula (1) in 4.2.7, by replacing  $N_{data,j}$  by  $N_{TGL}[k]$ .

Then  $DN_{cm,il}[k] = -(Z_i - Z_{i-1})$  for  $i = 1$  to  $I$

The total number of bits  $DN_{cm,il}^{TTI}$  corresponding to the gaps for compressed mode for TrCh  $i$  in the whole TTI is calculated as:

$$DN_{cm,il}^{TTI} = \sum_{k=0}^{F_i-1} DN_{cm,il}[k]$$

If  $DN_{il}^{TTI} = |DN_{cm,il}^{TTI}|$ , then, for TrCH  $i$  at TF  $l$ , the output data of the rate matching is the same as the input data and the rate matching algorithm of section 4.2.7.5 does not need to be executed. If  $DN_{il}^{TTI} \neq |DN_{cm,il}^{TTI}|$ , the parameters listed in sections 4.2.7.2.2.1 and 4.2.7.2.2.2 shall be used for determining  $e_{ini}$ ,  $e_{plus}$ , and  $e_{minus}$

#### 4.2.7.2.2.34 Determination of rate matching parameters for $\Psi$ uncoded and convolutionally encoded TrCHs

$$\Delta N_i = \Delta N_{il}^{TTI}$$

In Compressed Mode by puncturing, the following relation is used instead of the previous one:

$$DN_i = DN_{il}^{TTI} + DN_{cm,il}^{TTI}$$

$$a=2$$

For each transmission time interval of TrCH  $i$  with TF  $l$ , the rate-matching pattern is calculated with the algorithm in section 4.2.7.5. The following parameters are used as input:

$$X_i = N_{il}^{TTI}$$

$$e_{ini} = 1$$

$$e_{plus} = a \cdot N_{il}^{TTI}$$

$$e_{minus} = a \cdot |\Delta N_i|$$

puncturing for  $\Delta N_i < 0$ , repetition otherwise.

#### 4.2.7.2.2.24 Determination of rate matching parameters for Turbo encoded TrCHs

If repetition is to be performed on turbo encoded TrCHs, i.e.  $\Delta N_{il}^{TTI} > 0$ , the parameters in section 4.2.7.2.2.1 are used.

If puncturing is to be performed, the parameters below shall be used. Index  $b$  is used to indicate systematic ( $b=1$ ), 1<sup>st</sup> parity ( $b=2$ ), and 2<sup>nd</sup> parity bit ( $b=3$ ).

$$a=2 \text{ when } b=2$$

$$a=1 \text{ when } b=3$$

The bits indicated by  $b=1$  shall not be punctured.

$$\Delta N_i = \begin{cases} \left\lfloor \frac{\Delta N_{il}^{TTI}}{2} \right\rfloor, & b=2 \\ \left\lfloor \frac{\Delta N_{il}^{TTI}}{2} \right\rfloor, & b=3 \end{cases}$$

In Compressed Mode by puncturing, the following relations are used instead of the previous ones:

$$\underline{DN}_i = \underline{eDN}_{il}^{TTI}/2 \hat{u} + \underline{eDN}_{cm,il}^{TTI}/2 \hat{u}, \quad b=2$$

$$\underline{DN}_i = \underline{eDN}_{il}^{TTI}/2 \hat{u} + \underline{eDN}_{cm,il}^{TTI}/2 \hat{u}, \quad b=3$$

For each transmission time interval of TrCH  $i$  with TF  $l$ , the rate-matching pattern is calculated with the algorithm in section 4.2.7.5. The following parameters are used as input:

$$X_i = N_{il}^{TTI} / 3N,$$

$$e_{ini} = X_i,$$

$$e_{plus} = a \cdot X_i$$

$$e_{minus} = a \cdot |\Delta N_i|$$

#### 4.2.7.3 Bit separation and collection in uplink

The systematic bits (excluding bits for trellis termination) of turbo encoded TrCHs shall not be punctured. The systematic bit, first parity bit, and second parity bit in the bit sequence input to the rate matching block are therefore separated from each other. Puncturing is only applied to the parity bits and systematic bits used for trellis termination.

The bit separation function is transparent for uncoded TrCHs, convolutionally encoded TrCHs, and for turbo encoded TrCHs with repetition. The bit separation and bit collection are illustrated in figures 6 and 7.

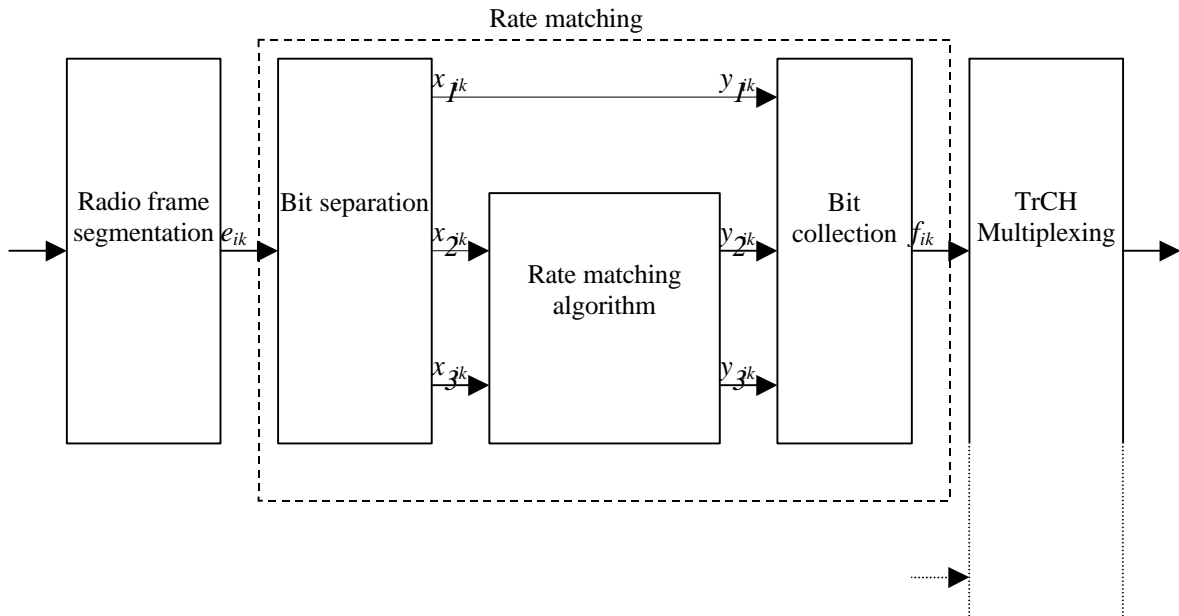

Figure 6: Puncturing of turbo encoded TrCHs

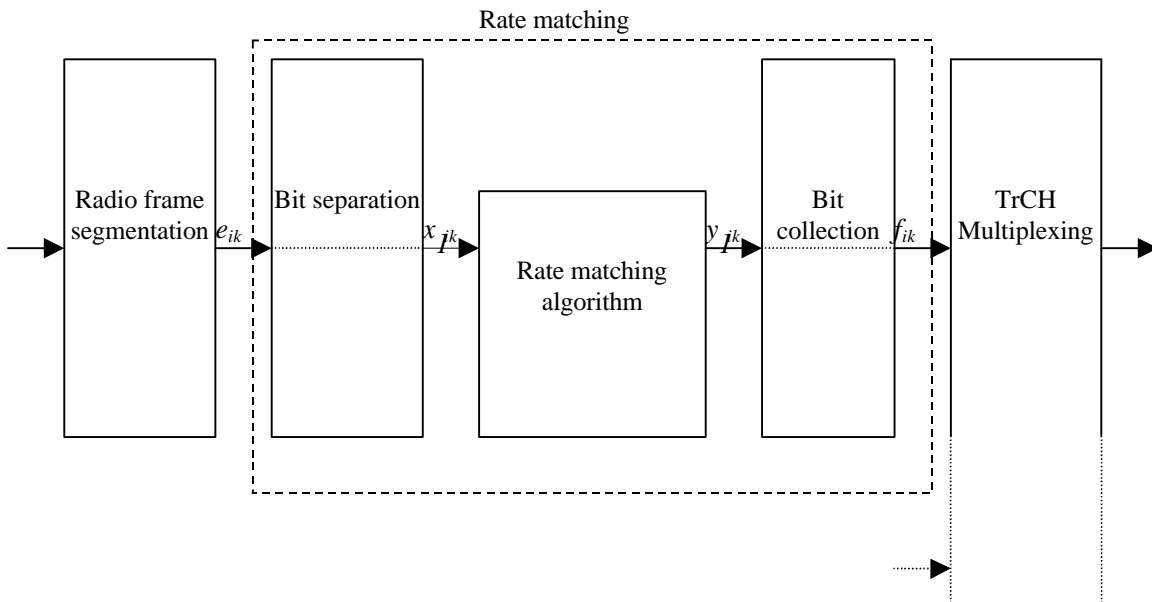

Figure 7: Rate matching for uncoded TrCHs, convolutionally encoded TrCHs, and for turbo encoded TrCHs with repetition.

The bit separation is dependent on the 1<sup>st</sup> interleaving and offsets are used to define the separation for different TTIs. The offsets  $a_b$  for the systematic ( $b=1$ ) and parity bits ( $b \in \{2, 3\}$ ) are listed in table 4.

Table 4: TTI dependent offset needed for bit separation

TTI (ms)	$a_1$	$a_2$	$a_3$
10, 40	0	1	2
20, 80	0	2	1

The bit separation is different for different radio frames in the TTI. A second offset is therefore needed. The radio frame number for TrCH  $i$  is denoted by  $n_i$ , and the offset by  $b_{n_i}$ .

Table 5: Radio frame dependent offset needed for bit separation

TTI (ms)	$b_0$	$b_1$	$b_2$	$b_3$	$b_4$	$b_5$	$b_6$	$b_7$
10	0	NA	NA	NA	NA	NA	NA	NA
20	0	1	NA	NA	NA	NA	NA	NA
40	0	1	2	0	NA	NA	NA	NA
80	0	1	2	0	1	2	0	1

#### 4.2.7.3.1 Bit separation

The bits input to the rate matching are denoted by  $e_{i1}, e_{i2}, e_{i3}, \dots, e_{iN_i}$ , where  $i$  is the TrCH number and  $N_i$  is the number of bits input to the rate matching block. Note that the transport format combination number  $j$  for simplicity has been left out in the bit numbering, i.e.  $N_i = N_{ij}$ . The bits after separation are denoted by  $x_{bi1}, x_{bi2}, x_{bi3}, \dots, x_{biX_i}$ . For turbo encoded TrCHs with puncturing,  $b$  indicates systematic, first parity, or second parity bit. For all other cases  $b$  is defined to be 1.  $X_i$  is the number of bits in each separated bit sequence. The relation between  $e_{ik}$  and  $x_{bik}$  is given below.

For turbo encoded TrCHs with puncturing:

$$x_{1,i,k} = e_{i,3(k-1)+1+(a_1+b_{n_i}) \bmod 3} \quad k = 1, 2, 3, \dots, X_i \quad X_i = \lfloor N_i / 3 \rfloor$$

$$x_{1,i,\lfloor N_i/3 \rfloor+k} = e_{i,3\lfloor N_i/3 \rfloor+k} \quad k = 1, \dots, N_i \bmod 3 \quad \text{Note: When } (N_i \bmod 3) = 0 \text{ this row is not needed.}$$

$$x_{2,i,k} = e_{i,3(k-1)+1+(a_2+b_{n_i}) \bmod 3} \quad k = 1, 2, 3, \dots, X_i \quad X_i = \lfloor N_i / 3 \rfloor$$

$$x_{3,i,k} = e_{i,3(k-1)+1+(a_3+b_{n_i}) \bmod 3} \quad k = 1, 2, 3, \dots, X_i \quad X_i = \lfloor N_i / 3 \rfloor$$

For uncoded TrCHs, convolutionally encoded TrCHs, and turbo encoded TrCHs with repetition:

$$x_{1,i,k} = e_{i,k} \quad k = 1, 2, 3, \dots, X_i \quad X_i = N_i$$

#### 4.2.7.3.2 Bit collection

The bits  $x_{bik}$  are input to the rate matching algorithm described in section 4.2.7.5. The bits output from the rate matching algorithm are denoted  $y_{bi1}, y_{bi2}, y_{bi3}, \dots, y_{biY_i}$ .

Bit collection is the inverse function of the separation. The bits after collection are denoted by  $z_{bi1}, z_{bi2}, z_{bi3}, \dots, z_{biY_i}$ .

After bit collection, the bits indicated as punctured are removed and the bits are then denoted by  $f_{i1}, f_{i2}, f_{i3}, \dots, f_{iV_i}$ , where  $i$  is the TrCH number and  $V_i = N_{ij} + DN_{ij}$ . The relations between  $y_{bik}$ ,  $z_{bik}$ , and  $f_{ik}$  are given below.

For turbo encoded TrCHs with puncturing ( $Y_i = X_i$ ):

$$z_{i,3(k-1)+1+(a_1+b_{n_i}) \bmod 3} = y_{1,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

$$z_{i,3\lfloor N_i/3 \rfloor+k} = y_{1,i,\lfloor N_i/3 \rfloor+k} \quad k = 1, \dots, N_i \bmod 3 \quad \text{Note: When } (N_i \bmod 3) = 0 \text{ this row is not needed.}$$

$$z_{i,3(k-1)+1+(a_2+b_{n_i}) \bmod 3} = y_{2,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

$$z_{i,3(k-1)+1+(a_3+b_{n_i}) \bmod 3} = y_{3,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

After the bit collection, bits  $z_{i,k}$  with value  $d$ , where  $d \in \{0, 1\}$ , are removed from the bit sequence. Bit  $f_{i,1}$  corresponds to the bit  $z_{i,k}$  with smallest index  $k$  after puncturing, bit  $f_{i,2}$  corresponds to the bit  $z_{i,k}$  with second smallest index  $k$  after puncturing, and so on.

For uncoded TrCHs, convolutionally encoded TrCHs, and turbo encoded TrCHs with repetition:

$$z_{i,k} = y_{1,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

When repetition is used,  $f_{i,k}=z_{i,k}$  and  $Y_i=V_i$ .

When puncturing is used,  $Y_i=X_i$  and bits  $z_{i,k}$  with value  $\mathbf{d}$ , where  $\mathbf{d} \in \{0, 1\}$ , are removed from the bit sequence. Bit  $f_{i,1}$  corresponds to the bit  $z_{i,k}$  with smallest index  $k$  after puncturing, bit  $f_{i,2}$  corresponds to the bit  $z_{i,k}$  with second smallest index  $k$  after puncturing, and so on.

#### 4.2.7.4 Bit separation and collection in downlink

The systematic bits (excluding bits for trellis termination) of turbo encoded TrCHs shall not be punctured. The systematic bit, first parity bit, and second parity bit in the bit sequence input to the rate matching block are therefore separated from each other. Puncturing is only applied to the parity bits and systematic bits used for trellis termination.

The bit separation function is transparent for uncoded TrCHs, convolutionally encoded TrCHs, and for turbo encoded TrCHs with repetition. The bit separation and bit collection are illustrated in figures 8 and 9.

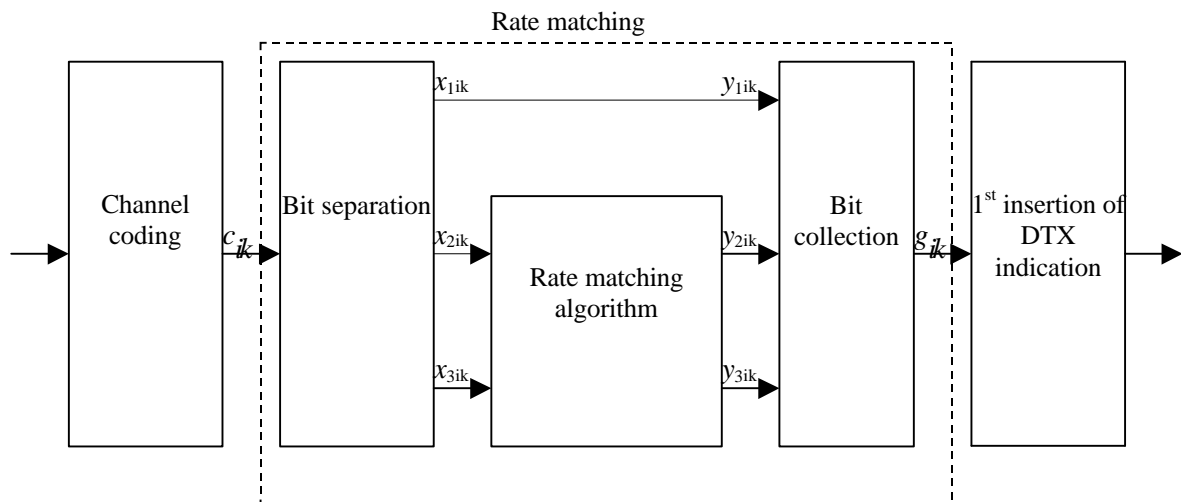

Figure 8: Puncturing of turbo encoded TrCHs

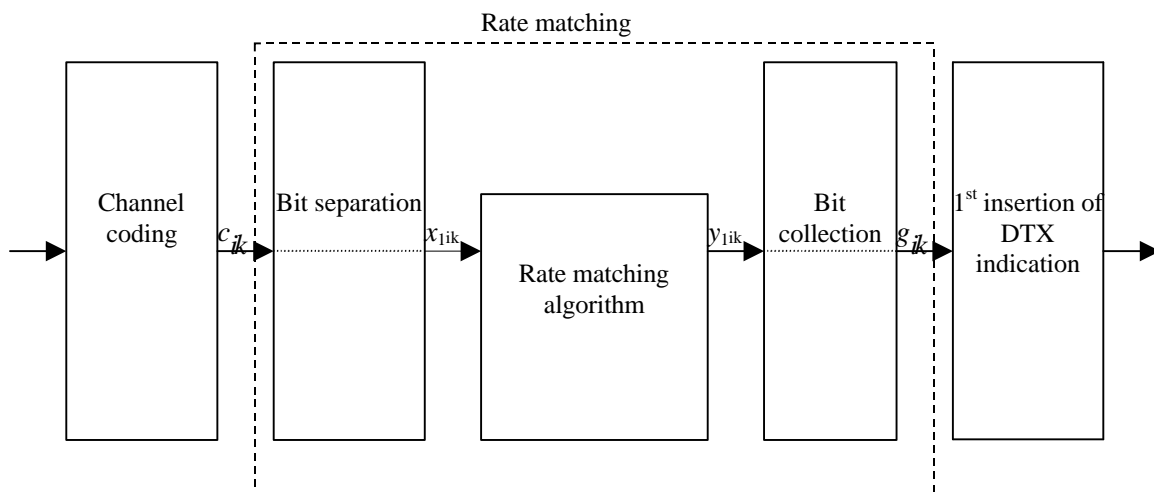

Figure 9: Rate matching for uncoded TrCHs, convolutionally encoded TrCHs, and for turbo encoded TrCHs with repetition.

#### 4.2.7.4.1 Bit separation

The bits input to the rate matching are denoted by  $c_{i1}, c_{i2}, c_{i3}, \dots, c_{iE_i}$ , where  $i$  is the TrCH number and  $E_i$  is the number of bits input to the rate matching block. Note that  $E_i$  is a multiple of 3 for turbo encoded TrCHs and that the transport format combination number  $j$  for simplicity has been left out in the bit numbering, i.e.  $E_i = N_{ij}$ . The bits after separation are denoted by  $x_{bi1}, x_{bi2}, x_{bi3}, \dots, x_{biX_i}$ . For turbo encoded TrCHs with puncturing,  $b$  indicates systematic, first parity, or second parity bit. For all other cases  $b$  is defined to be 1.  $X_i$  is the number of bits in each separated bit sequence. The relation between  $c_{ik}$  and  $x_{bik}$  is given below.

For turbo encoded TrCHs with puncturing:

$$x_{1,i,k} = c_{i,3(k-1)+1} \quad k = 1, 2, 3, \dots, X_i \quad X_i = E_i / 3$$

$$x_{2,i,k} = c_{i,3(k-1)+2} \quad k = 1, 2, 3, \dots, X_i \quad X_i = E_i / 3$$

$$x_{3,i,k} = c_{i,3(k-1)+3} \quad k = 1, 2, 3, \dots, X_i \quad X_i = E_i / 3$$

For uncoded TrCHs, convolutionally encoded TrCHs, and turbo encoded TrCHs with repetition:

$$x_{1,i,k} = c_{i,k} \quad k = 1, 2, 3, \dots, X_i \quad X_i = E_i$$

#### 4.2.7.4.2 Bit collection

The bits  $x_{bik}$  are input to the rate matching algorithm described in section 4.2.7.5. The bits output from the rate matching algorithm are denoted  $y_{bi1}, y_{bi2}, y_{bi3}, \dots, y_{biY_i}$ .

Bit collection is the inverse function of the separation. The bits after collection are denoted by  $z_{bi1}, z_{bi2}, z_{bi3}, \dots, z_{biY_i}$ . After bit collection, the bits indicated as punctured are removed and the bits are then denoted by  $g_{i1}, g_{i2}, g_{i3}, \dots, g_{iG_i}$ , where  $i$  is the TrCH number and  $G_i = N_{ij} + DN_{ij}$ . The relations between  $y_{bik}$ ,  $z_{bik}$ , and  $g_{ik}$  are given below.

For turbo encoded TrCHs with puncturing ( $Y_i = X_i$ ):

$$z_{i,3(k-1)+1} = y_{1,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

$$z_{i,3(k-1)+2} = y_{2,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

$$z_{i,3(k-1)+3} = y_{3,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

After the bit collection, bits  $z_{i,k}$  with value  $\mathbf{d}$ , where  $\mathbf{d} \in \{0, 1\}$ , are removed from the bit sequence. Bit  $g_{i,1}$  corresponds to the bit  $z_{i,k}$  with smallest index  $k$  after puncturing, bit  $g_{i,2}$  corresponds to the bit  $z_{i,k}$  with second smallest index  $k$  after puncturing, and so on.

For uncoded TrCHs, convolutionally encoded TrCHs, and turbo encoded TrCHs with repetition:

$$z_{i,k} = y_{1,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

When repetition is used,  $g_{i,k} = z_{i,k}$  and  $Y_i = G_i$ .

When puncturing is used,  $Y_i = X_i$  and bits  $z_{i,k}$  with value  $\mathbf{d}$ , where  $\mathbf{d} \in \{0, 1\}$ , are removed from the bit sequence. Bit  $g_{i,1}$  corresponds to the bit  $z_{i,k}$  with smallest index  $k$  after puncturing, bit  $g_{i,2}$  corresponds to the bit  $z_{i,k}$  with second smallest index  $k$  after puncturing, and so on.

#### 4.2.7.5 Rate matching pattern determination

Denote the bits before rate matching by:

$x_{i1}, x_{i2}, x_{i3}, \dots, x_{iX_i}$ , where  $i$  is the TrCH number and  $X_i$  is the parameter given in sections 4.2.7.1 and 4.2.7.2.

The rate matching rule is as follows:

if puncturing is to be performed

$e = e_{ini}$       -- initial error between current and desired puncturing ratio

$m = 1$       -- index of current bit

do while  $m \leq X_i$

$e = e - e_{minus}$       -- update error

if  $e \leq 0$  then      -- check if bit number  $m$  should be punctured

set bit  $x_{i,m}$  to  $d$  where  $d \in \{0, 1\}$

$e = e + e_{plus}$       -- update error

end if

$m = m + 1$       -- next bit

end do

else

$e = e_{ini}$       -- initial error between current and desired puncturing ratio

$m = 1$       -- index of current bit

do while  $m \leq X_i$

$e = e - e_{minus}$       -- update error

do while  $e \leq 0$       -- check if bit number  $m$  should be repeated

repeat bit  $x_{i,m}$

$e = e + e_{plus}$       -- update error

end do

$m = m + 1$       -- next bit

end do

end if

A repeated bit is placed directly after the original one.

## 4.2.9 Insertion of discontinuous transmission (DTX) indication bits

In the downlink, DTX is used to fill up the radio frame with bits. The insertion point of DTX indication bits depends on whether fixed or flexible positions of the TrCHs in the radio frame are used. It is up to the UTRAN to decide for each CCH whether fixed or flexible positions are used during the connection. DTX indication bits only indicate when the transmission should be turned off, they are not transmitted.

### 4.2.9.1 1<sup>st</sup> insertion of DTX indication bits

This step of inserting DTX indication bits is used only if the positions of the TrCHs in the radio frame are fixed. With fixed position scheme a fixed number of bits is reserved for each TrCH in the radio frame.

The bits from rate matching are denoted by  $g_{i1}, g_{i2}, g_{i3}, \dots, g_{iG_i}$ , where  $G_i$  is the number of bits in one TTI of TrCH  $i$ .

Denote the number of bits in one radio frame of TrCH  $i$  by  $H_i$ . Denote  $D_i$  the number of bits output of the first DTX insertion block.

In normal or compressed mode by spreading factor reduction,  $H_i$  is constant and corresponds to the maximum number of bits from TrCH  $i$  in one radio frame for any transport format of TrCH  $i$ , and  $D_i = F_i * H_i$ .

In compressed mode by puncturing, additional puncturing is performed in the rate matching block. The empty positions resulting from the additional puncturing are used to insert p-bits in the first interleaving block, the DTX insertion is therefore limited to allow for later insertion of p-bits. Thus DTX bits are inserted until the total number of bits is  $D_i$  where  $D_i = F_i * H_i + DN_{cm, i, max}^{TTI}$ , and  $H_i = N_{i,*} + DN_{i,*}$ .

In compressed mode by higher layer scheduling, only a subset of the TFC Set is allowed. From this subset it is possible to derive which TFs on each TrCH that are allowed. The maximum number of bits belonging to one TTI of TrCH  $i$  for

the allowed TFs is denoted by  $X_i$ .  $H_i$  is then calculated as  $H_i = \left\lfloor \frac{X_i}{F_i} \right\rfloor$ , where  $F_i$  is the number of radio frames in a TTI

of TrCH  $i$ , and  $D_i = F_i * H_i$ .

The bits output from the DTX insertion are denoted by  $h_{i1}, h_{i2}, h_{i3}, \dots, h_{iD_i}$ . Note that these bits are three valued. They are defined by the following relations:

$$h_{ik} = g_{ik} \quad k = 1, 2, 3, \dots, G_i$$

$$h_{ik} = \mathbf{d} \quad k = G_i + 1, G_i + 2, G_i + 3, \dots, F_i H_i D_i$$

where DTX indication bits are denoted by  $\mathbf{d}$ . Here  $g_{ik} \in \{0, 1\}$  and  $\mathbf{d} \notin \{0, 1\}$ .

### 4.2.9.2 2<sup>nd</sup> insertion of DTX indication bits

The DTX indication bits inserted in this step shall be placed at the end of the radio frame. Note that the DTX will be distributed over all slots after 2<sup>nd</sup> interleaving.

The bits input to the DTX insertion block are denoted by  $s_1, s_2, s_3, \dots, s_S$ , where  $S$  is the number of bits from TrCH multiplexing. The number of PhCHs is denoted by  $P$  and the number of bits in one radio frame, including DTX indication bits, for each PhCH is denoted by  $U$ . The number of available bits on the PhCH is denoted by  $N_{data}$  and  $N_{data} = 15N_{data1} + 15N_{data2}$ , where  $N_{data1}$  and  $N_{data2}$  are defined in [25.211]. In normal mode  $U = N_{data}$ .

In normal mode  $R = \frac{N_{data,*}}{P} = 15N_{data1} + 15N_{data2}$ , where  $N_{data1}$  and  $N_{data2}$  are defined in [2].

For compressed mode,  $N'_{data,*}$  is defined as  $N'_{data,*} = P(15N'_{data1} + 15N'_{data2}) - N'_{data1}$  and  $N'_{data2}$  are the number of bits in the data fields of the slot format used for the current compressed mode, i.e. slot format A or B as defined in [2] corresponding to the Spreading Factor and the number of transmitted slots in use.

In compressed mode by puncturing, DTX shall be inserted until  $N'_{data,*}$  bits, since the exact room for the gap is already reserved thanks to the earlier insertion of the p-bits. Therefore R is defined as  $R = N'_{data,*} / P$ .

In compressed mode by SF reduction and by higher layer scheduling, additional DTX shall be inserted if the transmission time reduction method does not exactly create a transmission gap of the desired TGL. The number of bits available to the CCTrCH in one radio frame in compressed mode by SF reduction and by higher layer scheduling is

denoted by  $N_{data,*}^{cm}$  and  $R = \frac{N_{data,*}^{cm}}{P}$ . mode  $N_{data}$  is changed from the value in normal mode. The exact value of

$N_{data,*}^{cm}$  is dependent on the TGL and the transmission time reduction method, which are signalled from higher layers. It can be calculated as  $N_{data,*}^{cm} = N'_{data,*} - N_{TGL}$ .  $N_{TGL}$  is the number of bits that are located within the transmission gap is denoted  $N_{TGL}$  and defined as:

$$N_{TGL} = \begin{cases} \frac{TGL}{15} N'_{data,*} - \frac{TGL}{15} N_{data}, & \text{if } N_{first} + TGL \leq 15 \\ \frac{15 - N_{first}}{15} N'_{data,*} - \frac{15 - N_{first}}{15} N_{data}, & \text{in first frame if } N_{first} + TGL > 15 \\ \frac{TGL - (15 - N_{first})}{15} N'_{data,*} - \frac{TGL - (15 - N_{first})}{15} N_{data}, & \text{in second frame if } N_{first} + TGL > 15 \end{cases}$$

$N_{first}$  and  $TGL$  are defined in Section 4.4.

~~In compressed mode  $U = N_{data} - N_{TGL}$ .~~

The bits output from the DTX insertion block are denoted by  $w_1, w_2, w_3, \dots, w_{(PR)}$   ~~$w_1, w_2, w_3, \dots, w_{(PU)}$~~ . Note that these bits are four valued in case of compressed mode by puncturing, and three valued otherwise. They are defined by the following relations:

$$w_k = s_k \quad k = 1, 2, 3, \dots, S$$

$$w_k = \mathbf{d} \quad k = S+1, S+2, S+3, \dots, PUR$$

where DTX indication bits are denoted by  $\mathbf{d}$ . Here  $s_k \in \{0, 1, \mathbf{p}\}$  and  $\mathbf{d} \notin \{0, 1\}$ .

### 4.2.10 Physical channel segmentation

When more than one PhCH is used, physical channel segmentation divides the bits among the different PhCHs. The bits input to the physical channel segmentation are denoted by  $x_1, x_2, x_3, \dots, x_Y$ , where  $Y$  is the number of bits input to the physical channel segmentation block. The number of PhCHs is denoted by  $P$ .

The bits after physical channel segmentation are denoted  $u_{p1}, u_{p2}, u_{p3}, \dots, u_{pU}$ , where  $p$  is PhCH number and  $U$  is the number of bits in one radio frame for each PhCH, i.e.  $U = (Y - N_{TGL}) / P$  for compressed mode by puncturing, and  $U = \frac{Y}{P}$  otherwise. The relation between  $x_k$  and  $u_{pk}$  is given below.

For all modes, some bits of the input flow are mapped to each code until the number of bits on the code is  $V$ . For modes other than compressed mode by puncturing, all bits of the input flow are taken to be mapped to the codes. For compressed mode by puncturing, only the bits of the input flow not corresponding to bits  $p$  are taken to be mapped to the codes, each bit  $p$  is removed to ensure creation the gap required by the compressed mode, as described below.

Bits on first PhCH after physical channel segmentation:

$$u_{1k} = x_k \quad u_{1,k} \equiv x_{i, f(k)} \quad k = 1, 2, \dots, U$$

Bits on second PhCH after physical channel segmentation:

$$u_{2k} = x_{(k+U)} \quad u_{2,k} \equiv x_{i, f(k+U)} \quad k = 1, 2, \dots, U$$

...

Bits on the  $P^{th}$  PhCH after physical channel segmentation:

$$u_{Pk} = x_{(k+(P-1)U)} \quad u_{P,k} \equiv x_{i, f(k+(P-1)U)} \quad k = 1, 2, \dots, U$$

where  $f$  is such that :

- for modes other than compressed mode by puncturing,  $x_{i, f(k)} = x_{i, k}$ , i.e.  $f(k) = k$ , for all  $k$ .
- for compressed mode by puncturing, bit  $u_{1,1}$  corresponds to the bit  $x_{i,k}$  with smallest index  $k$  when the bits  $p$  are not counted, bit  $u_{1,2}$  corresponds to the bit  $x_{i,k}$  with second smallest index  $k$  when the bits  $p$  are not counted, and so on for bits  $u_{1,3}, \dots, u_{1,V}, u_{2,1}, u_{2,2}, \dots, u_{2,V}, \dots, u_{P,1}, u_{P,2}, \dots, u_{P,V}$ .

#### 4.2.10.1 Relation between input and output of the physical segmentation block in uplink

The bits input to the physical segmentation are denoted by  $s_1, s_2, s_3, \dots, s_S$ . Hence,  $x_k = s_k$  and  $Y = S$ .

#### 4.2.10.2 Relation between input and output of the physical segmentation block in downlink

The bits input to the physical segmentation are denoted by  $w_1, w_2, w_3, \dots, w_{(PU)}$ . Hence,  $x_k = w_k$  and  $Y = PU$ .
