Text proposal for Tx Diversity for DCH

Text Proposal for 25.221

5.2.4 Beamforming in Physical channels and Transmit Diversity

When DL beamforming or Tx Diversity is used <u>on a DPCH</u>, at least that the user to which beamforming <u>Tx</u> <u>Diversity</u> is applied and which has a dedicated channel-shall get one individual midamble shift according to chapter 5.2.3, even in DL.

Text proposal for 25.224

4.86.11 Forward Link Downlink Transmit Diversity for DPCH

Transmit diversity in the forward link provides means to achieve similar performance gains as the mobile-station receiver diversity without the complexity of a second mobile-station receiver. Furthermore, transmit diversity improves the SIR and increases the system capacity. Depending on the mobile station's distance to the base station, its speed, and the asymmetry ratio, selective transmit diversity (STD) can be employed.

With STD, the received signal power of reverse link is measured for each of the antennas at the BTS over every single reverse link interval (1 slot). The antenna with the highest signal level is used to transmit the forward link information for that link during the next interval over which the earrier is used for the forward link (1 or more slots). The basis for the gains from this type of diversity is the availability of information on the channel due to the use of the same frequency for reverse link and forward link. STD is applied only to dedicated physical channels. STD can be applied if the distance between the different transmit antennas is small enough so that the delay profile from each antenna is almost the same.

The transmitter structure to support transmit diversity for DPCH transmission is shown in Figure 1. Channel coding, interleaving and spreading are done as in non-diversity mode. The spread complex valued signal is fed to both TX antenna branches, and weighted with antenna specific weight factors w_1 and w_2 . The weight factors are complex valued signals (i.e., $w_i = a_i + jb_i$), in general. These weight factors are calculated on a per slot and per user basis.

The weight factors are determined by the Node B.

4.8.1 Determination of weight information

Selective Transmit Diversity (STD) and Transmit Adaptive Antennas (TxAA) are examples of transmit diversity schemes for dedicated physical channels.

4.8.1.1 STD weights

The weight vector will take only two values depending on the signal strength received by each antenna in the uplink slot. For each user, the antenna receiving the highest power will be selected (i.e. the corresponding weight will be set to 1).

	$\underline{\mathbf{W}}_{1}$	$\underline{\mathbf{W}}_{2}$
Antenna 1 receiving highest power	1	0
Antenna 2 receiving highest power	0	<u>1</u>

Table 1: STD weights for two TX antennas

4.8.1.2 TxAA weights

In a generic sense, the weight vector to be applied at the transmitter is the w that maximises:

$$\underline{\mathbf{P}} = \mathbf{w}^{\mathbf{H}} \mathbf{H}^{\mathbf{H}} \mathbf{H} \mathbf{w} \tag{1}$$

where

 $H=[h_1, h_2, 1]$

and where the column vector h_i represents the estimated uplink channel impulse response for the i'th transmission antenna, of length equal to the length of the channel impulse response.

<Editors Note: Other TX diversity schemes such as schemes for common channels and TXAA-are ffs>
