Ad-hoc meeting S3#15bis, Munich, 8-9 November, 2000

S3z000035

IMS authentication and integrity/confidentiality protection

Siemens contribution S3z000022
(Discussion/Decision)

Günther Horn, Dirk Kröselberg, Klaus Müller

Siemens AG, Corporate Technology

Competence Centre Security

S3z000022: Scope and pre-requisites

➤ **Scope: Questions to be answered**

- ◆ Which network entity should perform authentication and key agreement (AKA) with the UE for SIP registration of a (roaming) user?
- ◆ Which network entity should terminate the access integrity/confidentiality protection of SIP messages with the UE?

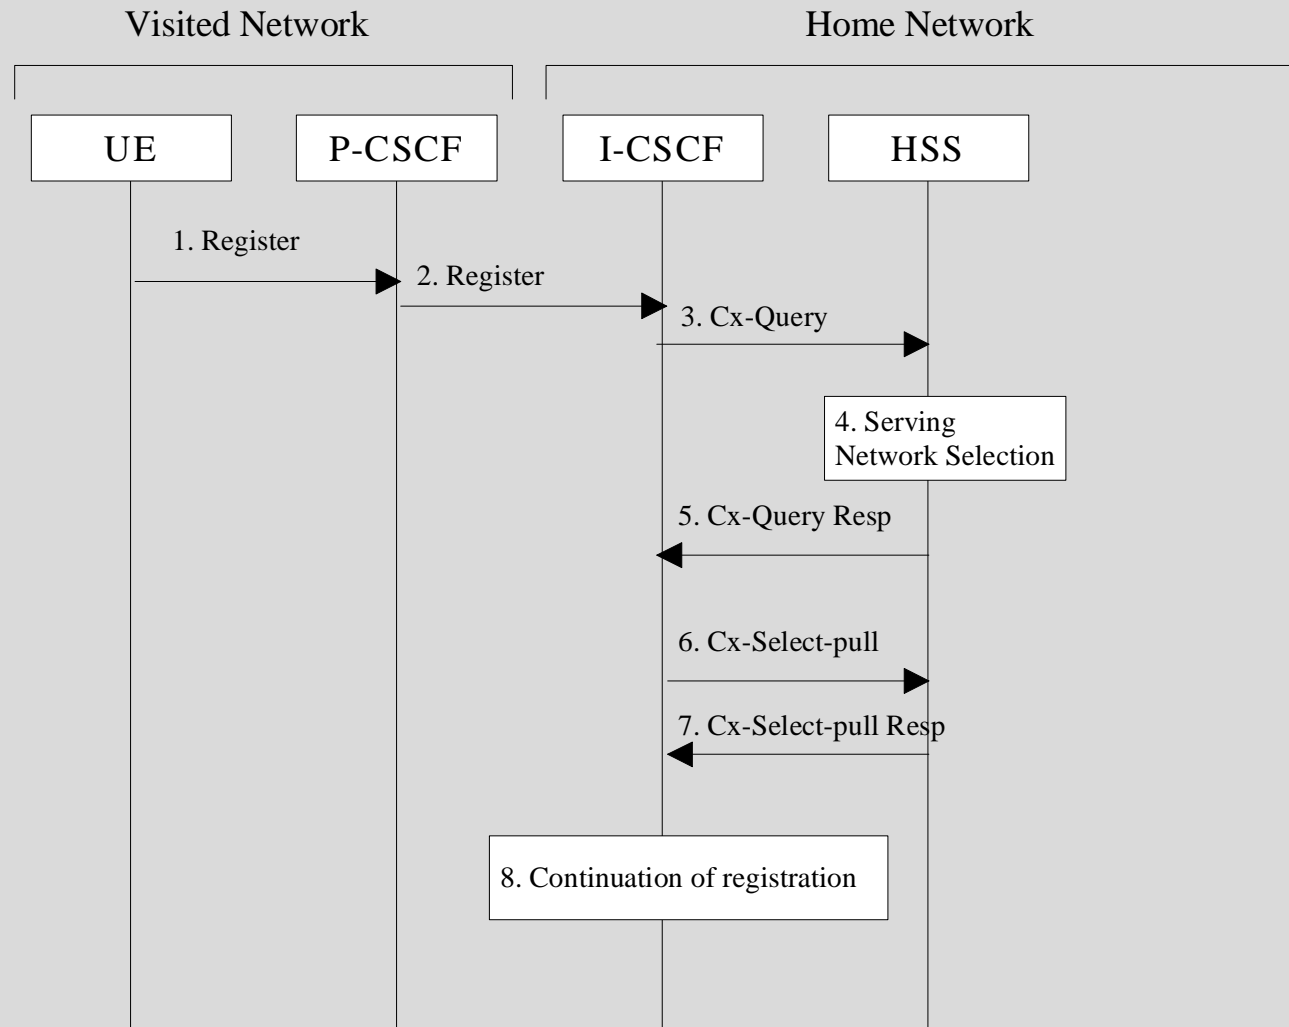

➤ **Pre-requisites: 3GPP SA 3 working assumption from [3G TR 33.8xx, section 8]**

- ◆ UMTS AKA protocol [3G TS 33.102] is performed through the SIP protocol (IMS AKA mechanism)
- ◆ A new authentication mode for SIP has to be standardised

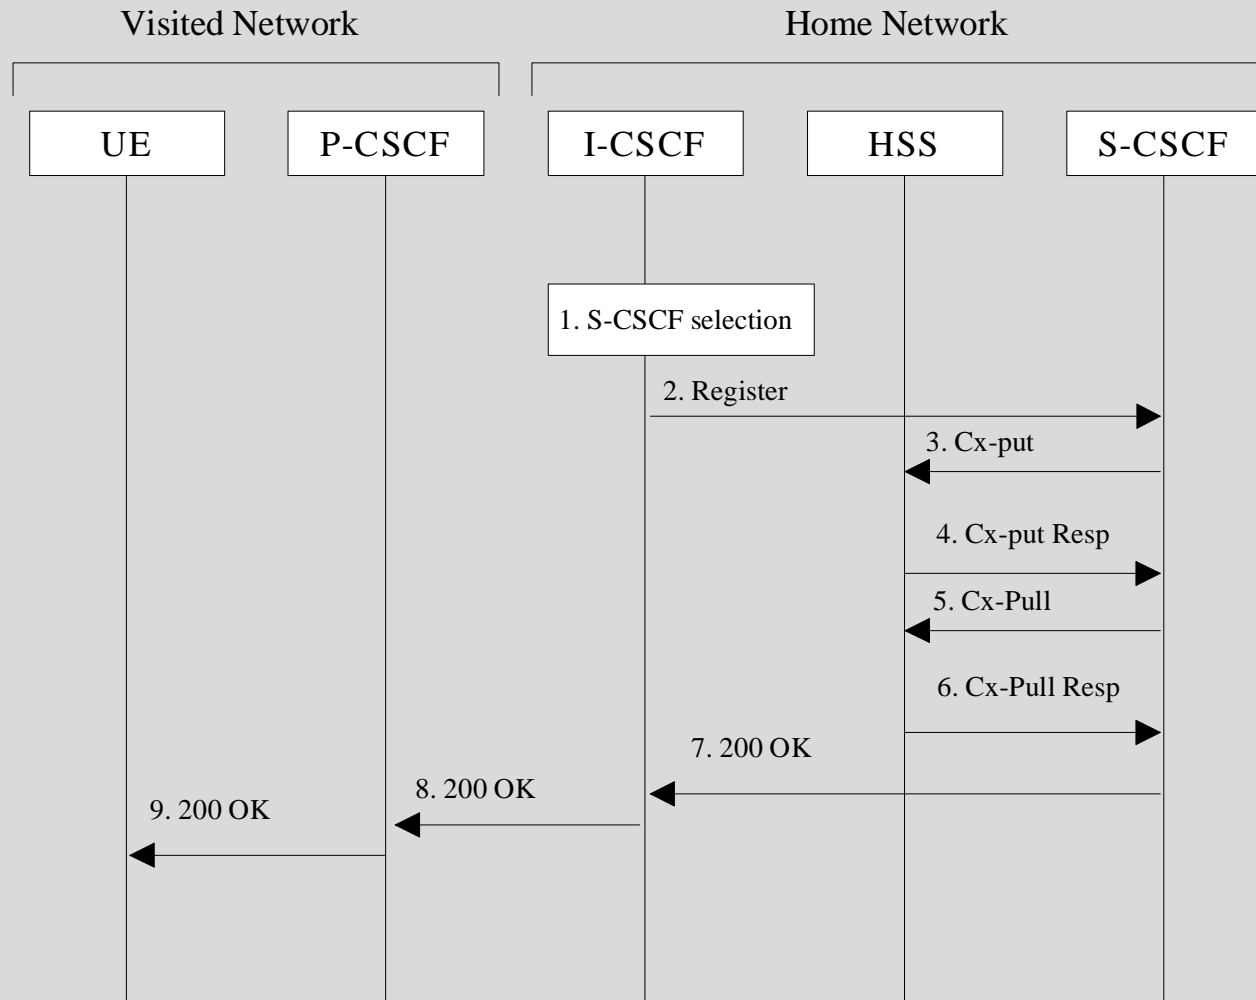

➤ **Siemens Proposal in S3z000022:**

- ◆ P-CSCF performs the IMS AKA with the UE and
- ◆ P-CSCF is the point of termination for integrity/confidentiality protection of SIP messages from the UE
- ◆ For the further SIP hops in the network, integrity/confidentiality protection shall be provided by network domain security features using IPsec.

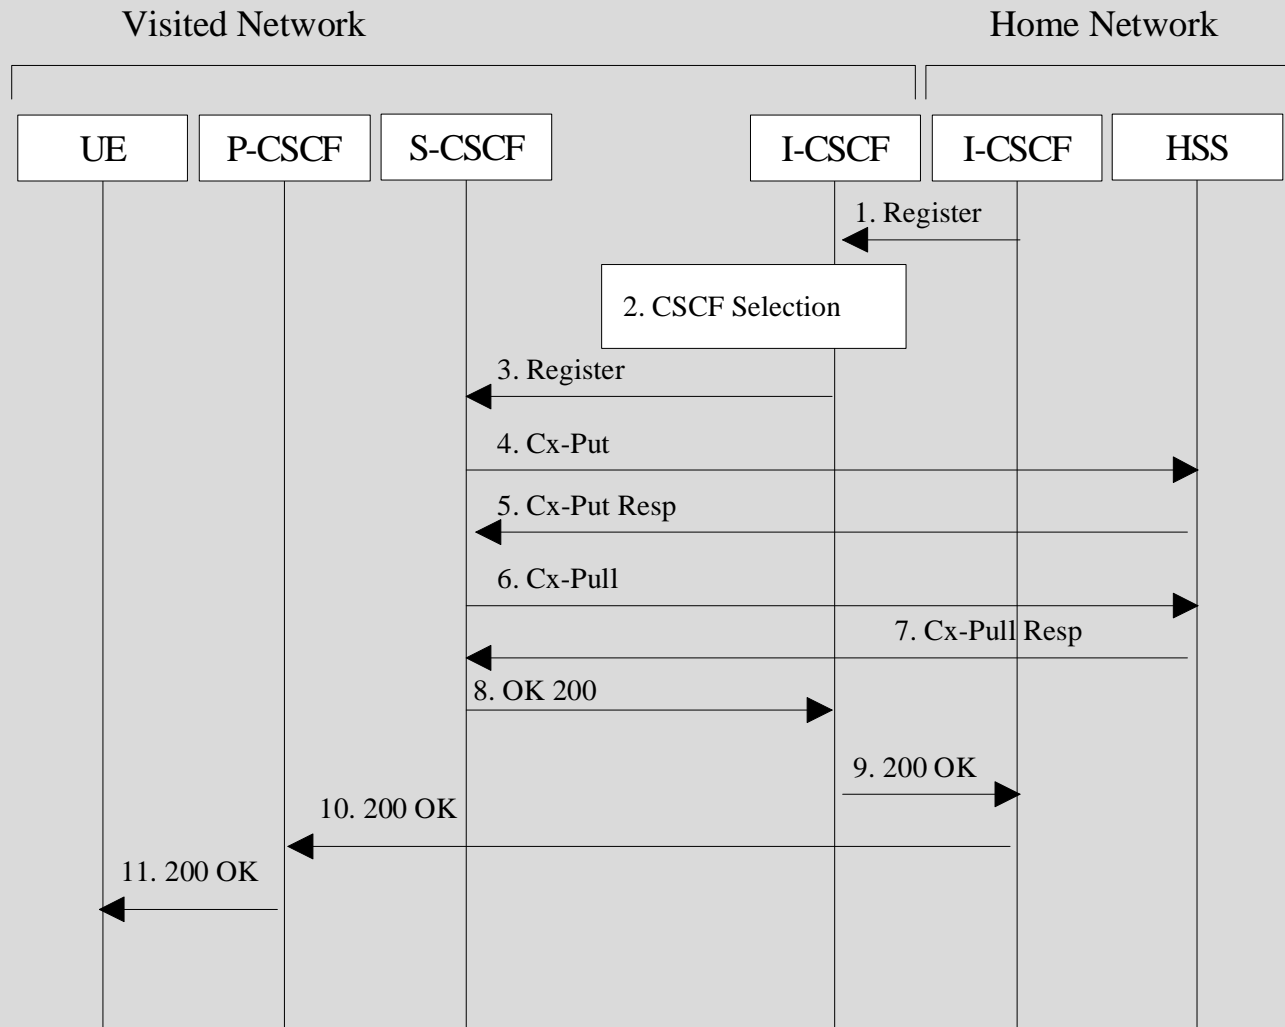

SIP Registration: Information flow without authentication (according to TR 23.228 v1.2.0, 10/2000)

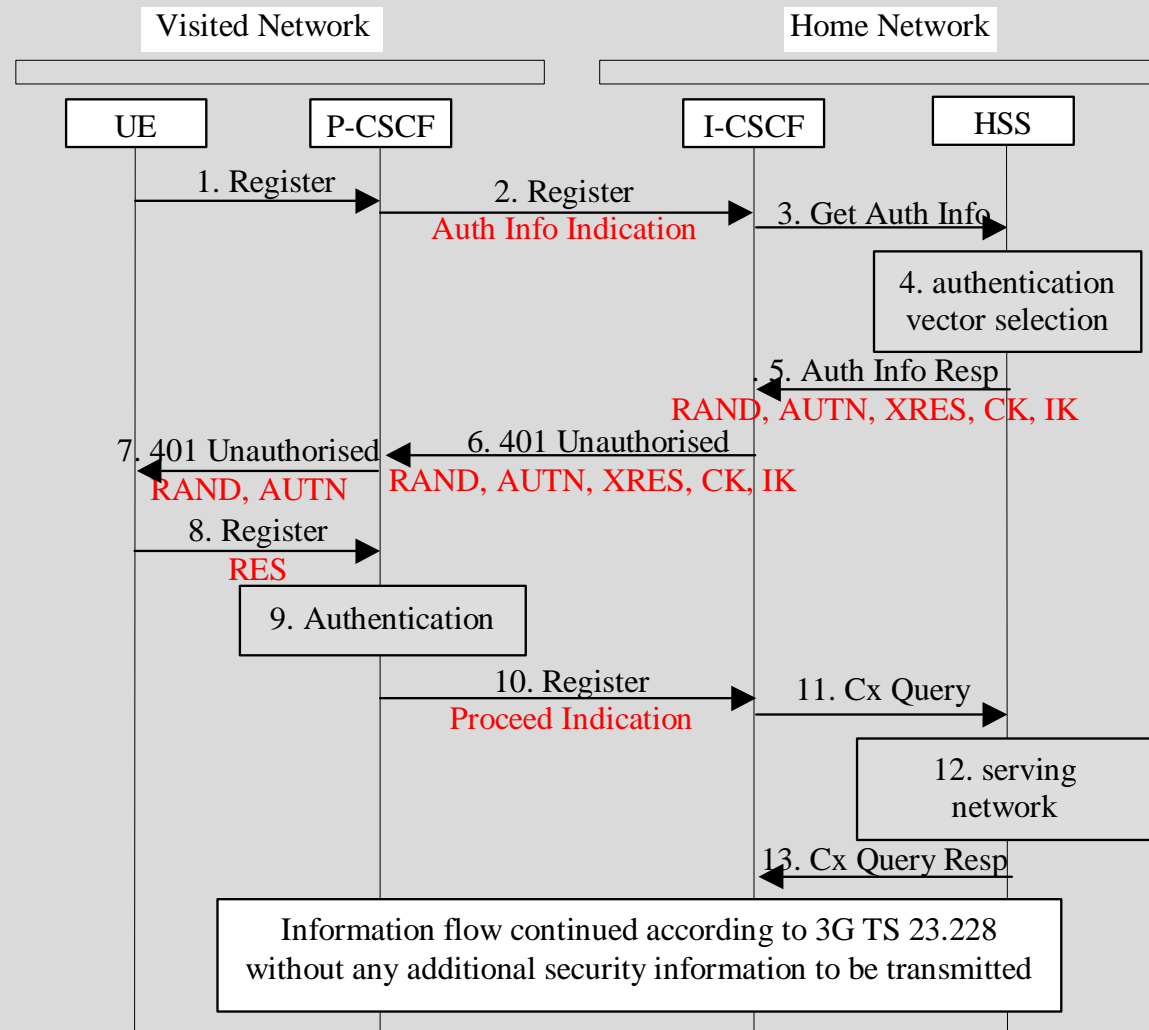

SIP Registration: Information flow without authentication (cont. for case S-CSCF in the home network)

SIP Registration: Information flow without authentication (cont. for case S-CSCF in the visited network)

SIP Registration: Information flow with authentication (No authentication information at P-CSCF)

Location of integrity/confidentiality functionality for IMS (1)

- **Drawbacks if confidentiality and integrity protection is not co-located in the same network entity**
 - ◆ Two different network entities have to be provided with the appropriate security functionality
 - ➔ Additional mechanisms required for control of access, secure storage, reliability, etc.
 - ◆ IMS equivalent to security mode set-up procedure in UMTS PS- and CS-domain has to be implemented in both network entities
(This feature still has to be defined for the IM domain!)
 - ◆ UE has to carry out the security mode set-up procedure twice
(once with each of the two network entities)
 - ◆ Key management for integrity and confidentiality keys could become complicated
 - ➔ UMTS re-authentication initiated by VLR or SGSN
 - ➔ Analogous feature required for IMS
 - ➔ Requires synchronisation between both network entities holding the session keys

Location of integrity/confidentiality functionality for IMS (2)

- **Additional cons for Ericsson proposal [S3z000010]
(additional to the ones mentioned in the last foil)**
 - ◆ Two different security related information flows have to be specified
 - ➔ S-CSCF may be located in visited or in home network
 - ◆ Not clear why one should have two different mechanisms, one at the application layer and one at the transport layer.
 - ◆ Seems odd to integrity-protect SIP messages twice, once at the application layer between the UE and the S-CSCF and a second time (optionally) by means of WTLS between the UE and the P-CSCF
 - ◆ Should be questioned whether WTLS is the right choice
 - ➔ WTLS necessitates another handshake to derive confidentiality and integrity keys from *CK* which is used as a master key for WTLS. This seems unnecessary.

Location of integrity/confidentiality functionality for IMS (3)

- **Reasons for terminating integrity/confidentiality protection with UE in P-CSCF**
 - ◆ Access network confidentiality protection with the UE should be terminated in the visited network, at least for lawful interception reasons
 - ➔ Only network entity always available in the visited network is the P-CSCF

- **Pros for Siemens proposal**
 - ◆ All the drawbacks on the last two foils are not valid for the Siemens proposal
 - ◆ The security related information flow is always the same
(Independent from the fact where the S-CSCF is located)

Location of IMS AKA functionality (1) Comparison between IMS AKA in P-CSCF or in HSS

- **Pros for IMS-AKA in the P-CSCF (Siemens proposal [S3z000022])**
 - ◆ Handling of the AKA seems to be a tolerable additional burden for the P-CSCF
 - ➔ P-CSCF has to be enhanced to handle the confidentiality and integrity functions anyway
 - ◆ Paradigm for AuC applied so far in UMTS and GSM could be preserved
 - ➔ HSS/AuC is just a database which responds to queries
 - ◆ No procedure to transfer the integrity/encryption keys required
 - ➔ All IMS security performed in P-CSCF (AKA as well as integrity/confidentiality protection)
 - ◆ Visited network can control lifetime of CK and IK by triggering a re-authentication; possible without having to contact the home network
 - ◆ Re-use of the mechanisms e.g. for generating security information in the HSS/AuC but also in the USIM possible
 - ➔ IMS AKA is analogous to UMTS authentication
 - ◆ Visited network has control over mobiles roaming in its network

Location of IMS AKA functionality (2) Comparison between IMS AKA in P-CSCF or in HSS

➤ **Cons for IMS-AKA in the HSS (Ericsson proposal [S3z000010])**

- ◆ Paradigm for AuC applied so far in UMTS and GSM could not be preserved
 - ➔ HSS/AuC is no longer just a database which responds to queries
- ◆ For each authentication attempt the home network HSS has to be contacted
- ◆ Procedure to transfer the integrity/encryption keys required
 - ➔ Integrity/confidentiality protection is located in an entity different from IMS AKA location
- ◆ HSS/AuC performance could be reduced
 - ➔ HSS/AuC has to send out requests and wait for responses, for a potentially large number of users simultaneously
- ◆ Re-authentication more complicated
 - ➔ The HSS has to be triggered by the visited network and the result has to be distributed to two different entities in the visited network
