## Foreword

This specification has been produced within the Third Generation Partnership Project (3GPP), and has been elaborated by the TSG RAN WG1 working group, as a part of the work in defining and describing Layer 1 of the Universal Mobile Terrestrial Radio Access (UTRA).

This report describes the transport channels and physical channels in UTRA/FDD Layer 1.

The following notations have been used for merging and editing:

- Original text from ETSI XX.03
  - [Text from XX.03 not agreed yet]
  - Text from ARIB Vol.3
  - [Text from ARIB Vol.3 not agreed yet]
  - <Editors note: for S1.11>
  - New merged text proposal by the editor.
- 

## 1 Scope

This document establishes the characteristics of the Layer 1 transport channels and physical channels in the FDD mode of UTRA. The main objectives of the document are to be a part of the full description of the UTRA Layer 1, and to serve as a basis for the drafting of the actual technical specification (TS).

---

## 2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, subsequent revisions do apply.
- A non-specific reference to an ETS shall also be taken to refer to later versions published as an EN with the same number.

## 3 Definitions, symbols and abbreviations

### 3.1 Definitions

For the purposes of the present document, the following definitions apply:

<defined term>: <definition>.

### 3.2 Symbols

For the purposes of the present document, the following symbols apply:

<symbol>            <Explanation>

### 3.3 Abbreviations

For the purposes of the present document, the following abbreviations apply:

[AICH	Acquisition Indication Channel]
BCH	Broadcast Channel
CCPCH	Common Control Physical Channel
DCH	Dedicated Channel
DPCCH	Dedicated Physical Control Channel
DPCH	Dedicated Physical Channel
DPDCH	Dedicated Physical Data Channel
DSCH	Downlink Shared Channel

FACH	Forward Access Channel
[FAUSCH	Fast Uplink Signalling Channel]
[FBI	Feedback Information]
MUI	Mobile User Identifier
PCH	Paging Channel
[PDSCH	Physical Downlink Shared Channel]
PI	Paging Indication
PRACH	Physical Random Access Channel
[PSCCCH	Physical Shared Channel Control Channel]
RACH	Random Access Channel
RNC	Radio Network Controller
SCH	Synchronisation Channel
SF	Spreading Factor
SFN	System Frame Number
STTD	Space Time Transmit Diversity
TFCI	Transport Format Combination Indicator
TPC	Transmit Power Control
UE	User Equipment

## 4 Transport channels

*<Editors note: FAUSCH has been accepted in ETSI. The use of DCH and/or DSCH Control Channel to control the downlink shared channel DSCH is FFS in ETSI. FAUSCH and shared channels are FFS in ARIB.>*

Transport channels are the services offered by Layer 1 to the higher layers.

A transport channel is defined by how and with what characteristics data is transferred over the air interface. A general classification of transport channels is into two groups:

- Common Channels (where there is a need for in-band identification of the UEs when particular UEs are addressed) and
- Dedicated Channels (where the UEs are identified by the physical channel, i.e. code and frequency)

The transport channel configuration is shown in Fig. XX-1.

### 4.1 Dedicated transport channels

*<Editors note: ETSI.>*

[There are two types of dedicated transport channels: the Dedicated Channel (DCH) and the Fast Uplink Signalling Channel (FAUSCH).]

*<Editors note: ETSI.>*

[There exists only one type of dedicated transport channel, the Dedicated Channel (DCH).]

#### 4.1.1 DCH – Dedicated Channel

The Dedicated Channel (DCH) is a downlink or uplink transport channel that is used to carry user or control information between the network and the UE. [The DCH thus corresponds to the three channels Dedicated Traffic Channel (DTCH), Stand-Alone Dedicated Control Channel (SDCCH), and Associated Control Channel (ACCH) defined within ITU-R M.1035.] The DCH is transmitted over the entire cell or over only a part of the cell using lobe-forming antennas. The Dedicated Channel (DCH) is characterized by the possibility of fast rate change (every 10ms), fast power control and inherent addressing of UEs.

#### 4.1.2 FAUSCH – Fast Uplink Signalling Channel

*<Editors note: ETSI only>*

[The Fast Uplink Signalling Channel (FAUSCH) is an optional uplink transport channel that is used to carry control information from a UE. The FAUSCH is always received from the entire cell.]

## 4.2 Common transport channels

<Editors note: DSCH and DSCH control channels are defined by ETSI.>

There are six types of common transport channels: BCH, FACH, PCH, RACH, DSCH, and DSCH control channel.

### 4.2.1 BCH – Broadcast Channel

The Broadcast Channel (BCH) is a downlink transport channel that is used to broadcast system- and cell-specific information. The BCH is always transmitted over the entire cell with a low fixed bit rate.

### 4.2.2 FACH – Forward Access Channel

The Forward Access Channel (FACH) is a downlink transport channel that is used to carry control information to a UE when the system knows the location cell of the UE. The FACH may also carry short user packets. The FACH is transmitted over the entire cell or over only a part of the cell using lobe-forming antennas. The FACH uses slow power control and requires in-band identification of the UEs.

### 4.2.3 PCH – Paging Channel

The Paging Channel (PCH) is a downlink transport channel that is used to carry control information to a UE when the system does not know the location cell of the UE. The PCH is always transmitted over the entire cell. The PCH is designed to support efficient sleep mode procedures.

### 4.2.4 RACH – Random Access Channel

The Random Access Channel (RACH) is an uplink transport channel that is used to carry control information from the UE. The RACH may also carry short user packets. The RACH is always received from the entire cell. The RACH is characterized by a collision risk and by the use of open loop power control.

### 4.2.5 DSCH – Downlink Shared Channel

<Editors note: ETSI only>

[The downlink shared channel (DSCH) is a downlink transport channel shared by several Ues carrying dedicated control or traffic data.

Two possibilities exist for the DSCH:

- the DSCH is associated with a DCH,
- the DSCH is associated with a DSCH control channel.

It is for further study whether both possibilities are needed.]

### 4.2.6 DSCH Control Channel

<Editors note: ETSI only>

[The DSCH control channel is a downlink transport channel carrying control information to the UE for operating the DSCH when not associated with a DCH. Such control information corresponds among other things to resource allocation messages and L1 control information such as TPC, that are not available on the DSCH.]

## 5 Physical channels

<Editors note: The naming and grouping of physical channels is somehow different in ARIB and ETSI. However, for the agreed common functionality there is a direct correspondance which is shown below. The editors proposal is to use the ETSI physical channels.>

- Perch CH (ARIB):                      Primary CCPCH and SCH (ETSI)
- Common Physical CH (ARIB):      Secondary CCPCH and PRACH (ETSI)
- Dedicated Physical CH (ARIB):    DPCCH and DPDCH (ETSI)

Other channels (FAUSCH, shared and AICH) are FFS.>

<Editors note: ARIB>

[Physical channels typically consist of a three-layer structure of superframes, radio frames, and timeslots, although this is not true for all physical channels. Depending on the symbol rate of the physical channel, the configuration of radio frames or timeslots varies.

- Superframe :    Superframe is a maximum frame unit with 720ms time period. A superframe consists of 72 radio frames, and is decided based on SFN.
- The head radio frame of superframe :    SFN mod 72=0.
- The tail radio frame of superframe: SFN mod 72=71.
- Radio frame :    Radio frame is a processing unit which consists of 16 time slots.

- Time slot : Time slot is a unit which consists of the set of information symbols. The number of symbols per time slot depends on the physical channels.
- Symbol : One symbol consists of a number of chips. The number of chips per symbol is equivalent to the spreading factor of the physical channels.]

## 5.1 The physical resource

The basic physical resource is the code/frequency plane. In addition, on the uplink, different information streams may be transmitted on the I and Q branch. Consequently, a physical channel corresponds to a specific carrier frequency, code, and, on the uplink, relative phase (0 or  $\pi/2$ ).

## 5.2 Uplink physical channels

### 5.2.1 Dedicated uplink physical channels

There are two types of uplink dedicated physical channels, the uplink Dedicated Physical Data Channel (uplink DPDCH) and the uplink Dedicated Physical Control Channel (uplink DPCCH).

The DPDCH and the DPCCH are I/Q code multiplexed within each radio frame (see S1.13).

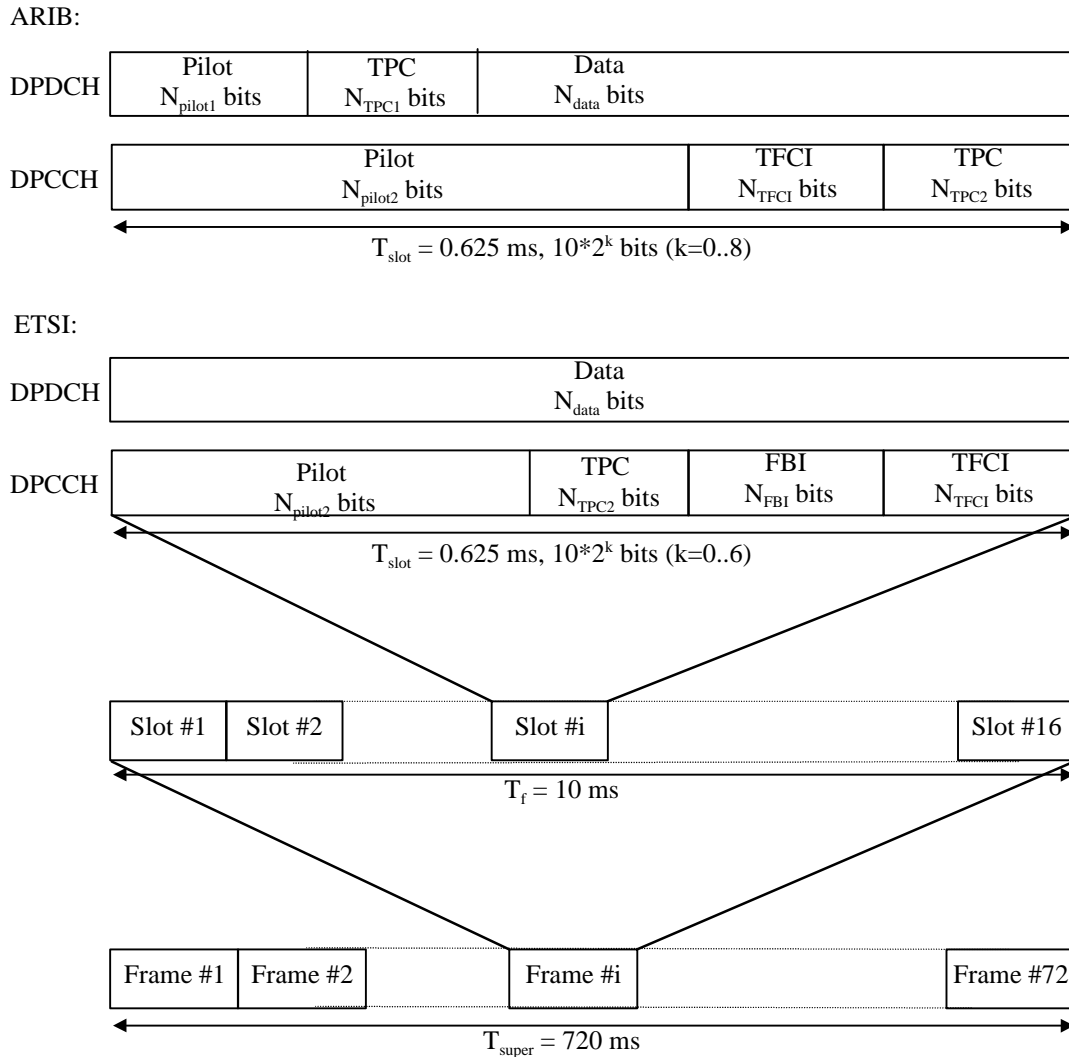

The uplink DPDCH is used to carry dedicated data generated at Layer 2 and above, i.e. the dedicated transport channel (DCH). There may be zero, one, or several uplink DPDCHs on each Layer 1 connection.

The uplink DPCCH is used to carry control information generated at Layer 1. The Layer 1 control information consists of known pilot bits to support channel estimation for coherent detection, transmit power-control (TPC) commands, feedback information (FBI), and an optional transport-format combination indicator (TFCI). The transport-format combination indicator informs the receiver about the instantaneous parameters of the different transport channels multiplexed on the uplink DPDCH, and corresponds to the data transmitted in the same frame. It is the UTRAN that determines if a TFCI should be transmitted, hence making it mandatory for all Ues to support the use of TFCI in the uplink. There is one and only one uplink DPCCH on each Layer 1 connection.

Figure 1 shows the frame structure of the uplink dedicated physical channels. Each frame of length 10 ms is split into 16 slots, each of length  $T_{\text{slot}} = 0.625$  ms, corresponding to one power-control period. A super frame corresponds to 72 consecutive frames, i.e. the super-frame length is 720 ms.

<Editors note: The different slot structures are discussed in Adhoc#7>

**Figure 1: Frame structure for uplink DPDCH/DPCCH.**

<Editors note: ETSI SF = 4-256, ARIB SF = 1-256. See Adhoc#7.>

The parameter  $k$  in Figure 1 determines the number of bits per uplink DPDCH/DPCCH slot. It is related to the spreading factor SF of the physical channel as  $SF = 256/2^k$ . The spreading factor may thus range from 256 down to  $\lfloor 4/1 \rfloor$ . Note that an uplink DPDCH and uplink DPCCH on the same Layer 1 connection generally are of different rates, i.e. have different spreading factors and different values of  $k$ .

The exact number of bits of the different uplink DPCCH fields in Figure 1 ( $N_{\text{pilot2}}$ ,  $N_{\text{TPC2}}$ ,  $N_{\text{FBI}}$ , and  $N_{\text{TFCI}}$ ) is yet to be determined. The spreading factor for the DPCCH fields and the length (in bits) of each field is negotiated at connection set up. Both the spreading factor and the length of the fields may be negotiated during the connection through higher layer signalling. A "reserved" field should be introduced, its length is to be defined and is currently assumed to be zero bits.

[The possibility of Pilot and TPC bits in the uplink DPDCH fields in Figure 1 ( $N_{\text{pilot1}}$ ,  $N_{\text{TPC1}}$ ) allows future enhancements.]

The  $N_{\text{FBI}}$  bits are used to support techniques requiring feedback between the UE and the UTRAN Access Point (=cell transceiver), including feedback (FB) mode transmit diversity, and site selection diversity. The exact details of the FBI field in the frame structure shown in Figure 1 are for further study.

<Editors note: The Tables 1~4 are defined in ARIB. It is proposed to use them as default values. See Ad Hoc#7.>

The default values for the number of bits per field are given in Table 1 and Table 2. The channel bit and symbol rates given in Table 1 are the rates immediately before spreading. The pilot patterns are given in Table 3 and the TPC bit pattern is given in Table 4.

*Table 1: DPDCH fields*

Channel Bit Rate (kbps)	Channel Symbol Rate (ksps)	SF	Bits/Frame	Bits/Slot	$N_{\text{pilot1}}$	$N_{\text{TPCI}}$	$N_{\text{data}}$
16	16	256	160	10	0	0	10
32	32	128	320	20	0	0	20
64	64	64	640	40	0	0	40
128	128	32	1280	80	0	0	80
256	256	16	2560	160	0	0	160
512	512	8	5120	320	0	0	320
1024	1024	4	10240	640	0	0	640
[2048]	[2048]	[2]	20480	1280	0	0	1280
[4096]	[4096]	[1]	40960	2560	0	0	2560

There are two types of Uplink Dedicated Physical Channels; those that include TFCI (e.g. for several simultaneous services) and those that do not include TFCI (e.g. for fixed-rate services). These types are reflected by the duplicated rows of Table 2. The channel bit and symbol rates given in Table 2 are the rates immediately before spreading.

Table 2: DPCCH fields

Channel Bit Rate (kbps)	Channel Symbol Rate (ksps)	SF	Bits/Frame	Bits/Slot	$N_{\text{pilot}}$	$N_{\text{TPC}}$	$N_{\text{TFCI}}$
16	16	256	160	10	6	2	2
16	16	256	160	10	8	2	0

The pilot bit pattern is described in Table 3. The shadowed part can be used as frame synchronization words. (The value of the pilot bit other than the frame synchronization word shall be "1".)

Table 3: Pilot bit pattern

Bit #	$N_{\text{pilot2}} = 6$						$N_{\text{pilot2}} = 8$							
	0	1	2	3	4	5	0	1	2	3	4	5	6	7
Slot #1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
2	1	1	1	1	0	1	1	1	1	1	1	0	1	1
3	1	0	1	1	0	1	1	0	1	1	1	0	1	1
4	1	1	0	1	0	1	1	1	0	1	0	1	1	1
5	1	1	0	1	1	1	1	1	0	1	1	1	1	1
6	1	1	0	1	1	1	1	1	0	1	1	1	1	1
7	1	0	1	1	0	0	1	0	1	1	0	1	0	1
8	1	1	0	1	0	1	1	1	1	0	1	0	1	1
9	1	1	1	1	0	0	1	1	1	1	0	1	0	0
10	1	0	1	1	0	1	1	0	1	1	1	0	1	1
11	1	1	1	1	1	0	1	1	1	1	1	1	1	0
12	1	0	1	1	0	1	1	0	1	1	1	0	1	1
13	1	0	0	1	0	1	1	0	1	0	1	0	1	1
14	1	1	0	1	0	0	1	1	1	0	1	0	1	0
15	1	0	1	1	0	0	1	0	1	1	1	0	1	0
16	1	0	0	1	0	0	1	0	1	0	1	0	1	0

The relationship between the TPC bit pattern and transmitter power control amount is presented in Table 4.

Table 4: TPC Bit Pattern

TPC Bit Pattern	Transmitter power control command
11	1 (Power up)
00	0 (Power down)

[TPC bits are allowed to be punctured. UE can utilize the vacant bits given by the puncturing in order to send control information to BTS. In case of the feedback mode of the transmission diversity, UE uses the vacant bits for Antenna Selection commands.]

In each radio frame, the TFCI value corresponds to a certain combination of bit rates of the DCHs currently in use. This correspondence is (re-)negotiated at each DCH addition/removal. For default TFCI there is one code word of length 32 bits. For extended TFCI there are 2 code words of length 16 bits giving the same total number of encoded TFCI bits per frame as for default TFCI. The 32 encoded TFCI bits are divided evenly among the 16 time slots, 2bits per slot.

Multi-code operation is possible for the uplink dedicated physical channels. When multi-code transmission is used, several parallel DPDCH are transmitted using different channelization codes, see S1.13UMTS XX.05. However, there is only one DPCCH per connection.

## 5.2.2 Common uplink physical channels

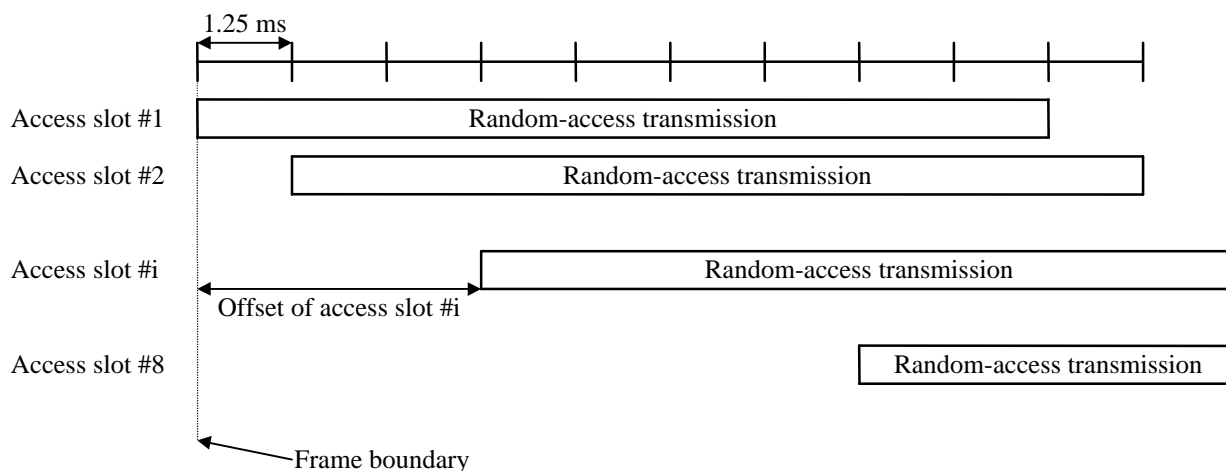

### 5.2.2.1 Physical Random Access Channel

<Editors note: This section has not been updated yet. see Adhoc #3. The whole section will be updated when the Adhoc#3 has decided upon RACH. FAUSCH is FFS outside ETSI.>

[The Physical Random Access Channel (PRACH) is used to carry the RACH and the FAUSCH. ]

#### 5.2.2.1.1 RACH transmission

The random-access transmission is based on a Slotted ALOHA approach with fast acquisition indication, i.e. a UE can start the transmission at a number of well-defined time-offsets, relative to the frame boundary of the received BCH of the current cell. The different time offsets are denoted *access slots* and are spaced 1.25 ms apart as illustrated in Figure 2. Information on what access slots are available in the current cell is broadcast on the BCH.

**Figure 2: PRACH allocated for RACH access slots.**

The structure of the random-access transmission of Figure 2, is shown in Figure 3. The random-access transmission consists of one or several *preambles* of length 1 ms and a *message* of length 10 ms.

**Figure 3: Structure of the random-access transmission.**

#### 5.2.2.1.2 RACH preamble part

The preamble part of the random-access burst consists of a *signature* of length 16 complex symbols  $\pm 1(+j)$ . Each preamble symbol is spread with a 256 chip real Orthogonal Gold code. There are a total of 16 different signatures, based on the Orthogonal Gold code set of length 16 (see UMTS XX.05 for more details).

### 5.2.2.1.3 RACH message part

The message part of the random-access burst has the same structure as the uplink dedicated physical channel. It consists of a data part, corresponding to the uplink DPDCH, and a Layer 1 control part, corresponding to the uplink DPCCH, see Figure 4. The data and control parts are transmitted in parallel. The data part carries the random access request or user packet. The spreading factor of the data part is limited to  $SF \in \{256, 128, 64, 32\}$  corresponding to channel bit rates of 16, 32, 64, and 128 kbps respectively. The control part carries pilot bits and rate information, using a spreading factor of 256. The rate information indicates which channelization code (or rather the spreading factor of the channelization code) is used on the data part, see further UMTS XX.05.

Figure 4: The message part of the random-access burst.

### 5.2.2.1.4 FAUSCH transmission

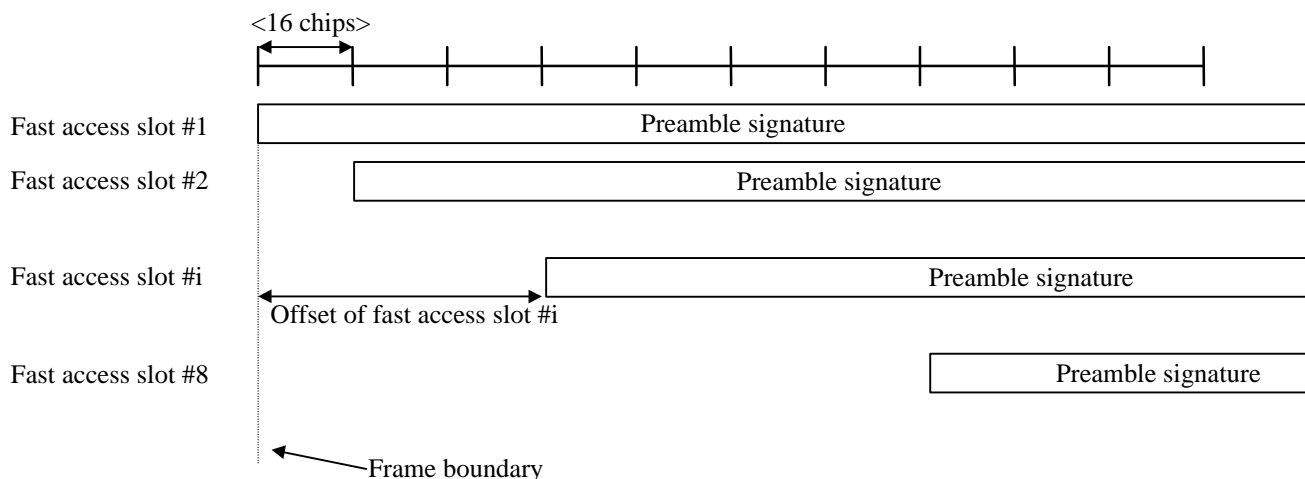

Figure 5: PRACH used for FAUSCH fast access slots.

The Fast Uplink Physical Channel (FAUSCH) is based on the transmission of a signature of length 16 complex symbols  $\pm(1+j)$ . The signature is one of the set of signatures used for the RACH preamble. Signature no.[8] is selected because it has the best correlation properties. Each symbol is spread with a 256 chip real Orthogonal Gold code. A time slot is allocated to the UE by the network when entering Connected Mode but the allocation may be updated with appropriate signalling. To avoid the possibility of collisions only one UE is allowed to transmit with a given signature in a particular time slot. Thus the UE can start the transmission of the FAUSCH at an assigned time offset relative to the frame boundary of the received BCH of the current cell. The different time offsets are denoted *fast access slots* and are spaced [16] chips apart as illustrated in Figure 5. To avoid possible confusion of transmissions from different UE's the separation between allocations of fast access slots to different UE's must be sufficient to allow for any round-trip delay resulting from the physical distance between network and UE. Therefore the allocation of fast access slots may be limited by the network to a subset of those available, depending on the deployment scenario.

### 5.2.2.1.5 Sharing of PRACH by RACH and FAUSCH

FAUSCH uses only the preamble part of PRACH. The RACH and FAUSCH transmissions could use different Gold Codes for spreading the signatures, but the complexity of the uplink receiver is significantly reduced if the same Gold Code is used. Low interference between RACH and FAUSCH can then be achieved by restricting the allocation of RACH access slots and FAUSCH fast access slots so that the respective transmissions occur in different parts of the 10 ms frame. The partitioning of the frame is flexible. For example, if RACH access slots are spaced 2.5 ms apart, then FAUSCH fast access slots could be allocated in the gaps. The UE can determine the available RACH access slots by monitoring the BCH. The FAUSCH fast access slots are individually allocated to a specific UE.

## 5.3 Downlink physical channels

### 5.3.1 Dedicated downlink physical channels

There is only one type of downlink dedicated physical channel, the Downlink Dedicated Physical Channel (downlink DPCH).

Within one downlink DPCH, dedicated data generated at Layer 2 and above, i.e. the dedicated transport channel (DCH), is transmitted in time-multiplex with control information generated at Layer 1 (known pilot bits, TPC commands, and an optional TFCI). The downlink DPCH can thus be seen as a time multiplex of a downlink DPDCH and a downlink DPCCH, compare Section 5.2.1. It is the UTRAN that determines if a TFCI should be transmitted, hence making it is mandatory for all Ues to support the use of TFCI in the downlink.

Figure 6 shows the frame structure of the downlink DPCH. Each frame of length 10 ms is split into 16 slots, each of length  $T_{\text{slot}} = 0.625$  ms, corresponding to one power-control period. A super frame corresponds to 72 consecutive frames, i.e. the super-frame length is 720 ms.

<Editors note: The different slot structures are discussed in Adhoc#7.>

ARIB:

ETSI:

**Figure 6: Frame structure for downlink DPCH.**

<Editors note: ETSI SF = 4-256, ARIB SF = 1-512. See Adhoc#7.>

The parameter  $k$  in Figure 6 determines the total number of bits per downlink DPCH slot. It is related to the spreading factor SF of the physical channel as  $SF = 256/2^k$ . The spreading factor may thus range from  $[512/256]$  down to  $[4/1]$ . The exact number of bits of the different downlink DPCH fields in Figure 6 ( $N_{\text{pilot}}$ ,  $N_{\text{TPC}}$ ,  $N_{\text{TFCI}}$ ,  $N_{\text{data1}}$  and  $N_{\text{data2}}$ ) is yet to be determined. The overhead due to the DPCCH transmission has to be negotiated at the connection set-up and can be re-negotiated during the communication, in order to match particular propagation conditions.

The DPCCH fields are spread using the same channelization code used for the DPDCH field. A channelization code for the highest bit rate to be served during the connection (for a given DPCH) should be assigned (with spreading factor  $SF_1$ ).

<Editors note: The Tables 5~7 are defined in ARIB. It is proposed to use them as default values. See Ad Hoc#7.>

Table 5 shows the default number of bits per slot of the various fields. There are basically two types of downlink Dedicated Physical Channel; those that include TFCI (e.g. for several simultaneous services) and those that do not include TFCI (e.g. for fixed-rate services). These types are reflected by the duplicated rows of Table 5. The channel bit and symbol rates given in Table 5 are the rates immediately before spreading.

Table 5: DPDCH and DPCCH fields

Channel Bit Rate (kbps)	Channel Symbol Rate (ksps)	SF	Bits/Frame			Bits/Slot	DPDCH Bits/Slot		DPCCH Bits/Slot		
			DPDCH	DPCCH	TOT		$N_{Data1}$	$N_{Data2}$	$N_{TFCI}$	$N_{TPC}$	$N_{Pilot}$
16	8	[512]	64	96	160	10	2	2	0	2	4
16	8	[512]	32	128	160	10	0	2	2	2	4

[The relationship between the TPC symbol and the transmitter power control amount is presented in Table 7.]

*Table 7: TPC Bit Pattern*

TPC Symbol	Transmitter power control command
11	1 (Power up)
00	0 (Power down)

In each radio frame, the TFCI value corresponds to a certain combination of bit rates of the DCHs currently in use. This correspondence is (re-)negotiated at each DCH addition/removal. For default TFCI there is one code word of length 32 bits. For extended TFCI there are 2 code words of length 16 bits giving the same total number of encoded TFCI bits per frame as for default TFCI. The 32 encoded TFCI bits are divided evenly among the 16 time slots, 2bits per slot. At the channel bit rates higher than 64 ksps, each 2-bit pair is repeated four times.

<Editors note: This should go to TX diversity. See Adhoc#6.>

[Note that connection-dedicated pilot bits are transmitted also for the downlink in order to support the use of downlink adaptive antennas.]

<Editors note: DL Multicode transmission>

When the total bit rate to be transmitted on one downlink connection exceeds the maximum bit rate for a downlink physical channel, multicode transmission is employed, i.e. several parallel downlink DPCHs are transmitted for one connection using the same spreading factor. In this case, the Layer 1 control information is put on only the first downlink DPCH. The additional downlink DPCHs belonging to the connection do not transmit any data during the corresponding time period, see Figure 7.

Multiple codes may also be transmitted in order to transmit different transport channels on different codes (code multiplex). In that case, the different parallel codes may have different spreading factors and the Layer 1 control information is transmitted on each code independently.

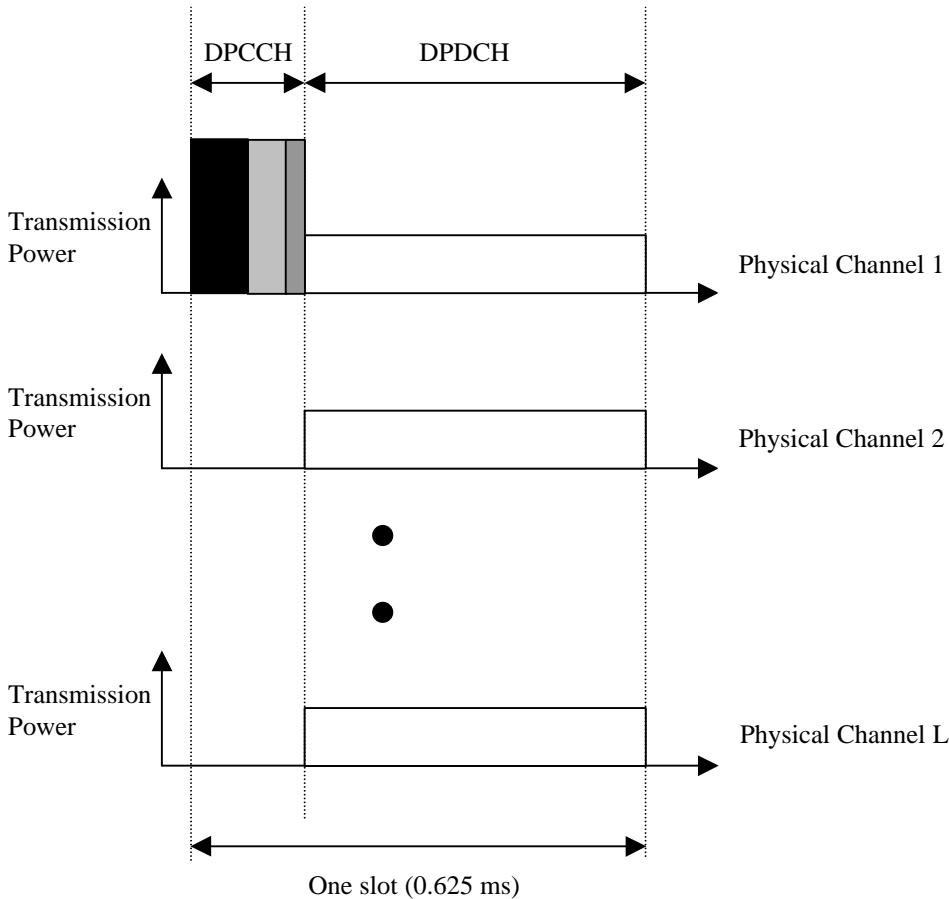

Figure 7: Downlink slot format in case of multi-code transmission.

### 5.3.1.1 Dedicated channel pilots with feedback mode transmit diversity

<Editors note: This section has not been updated yet. see Adhoc #6. The ARIB section 3.2.6.11.4 describes the TDTD scheme >

For certain sub-modes of feedback mode transmit diversity, in which transmission antennas are selected, the pilot patterns can be varied according to which antenna is transmitted upon (see Figure 8 a, where the different shading indicates different pilot patterns). This assists in some types of antenna verification (see XX.07 for a description of antenna verification). Pilot symbol patterns are TBD. Otherwise, the pilot symbol patterns from both of the antennas are the same (see Figure 8 b).

(a)

(b)

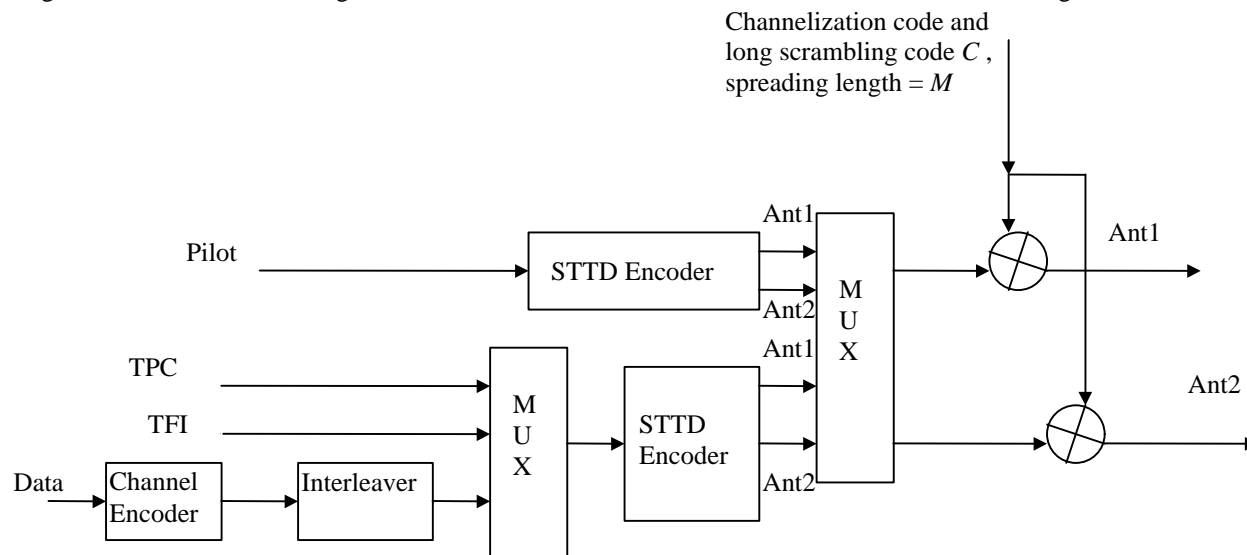

**Figure 8: Slot structures for downlink dedicated physical channel diversity transmission. Structure (a) may be used in conjunction with antenna verification. Structure (b) is used otherwise.<sup>1</sup>**

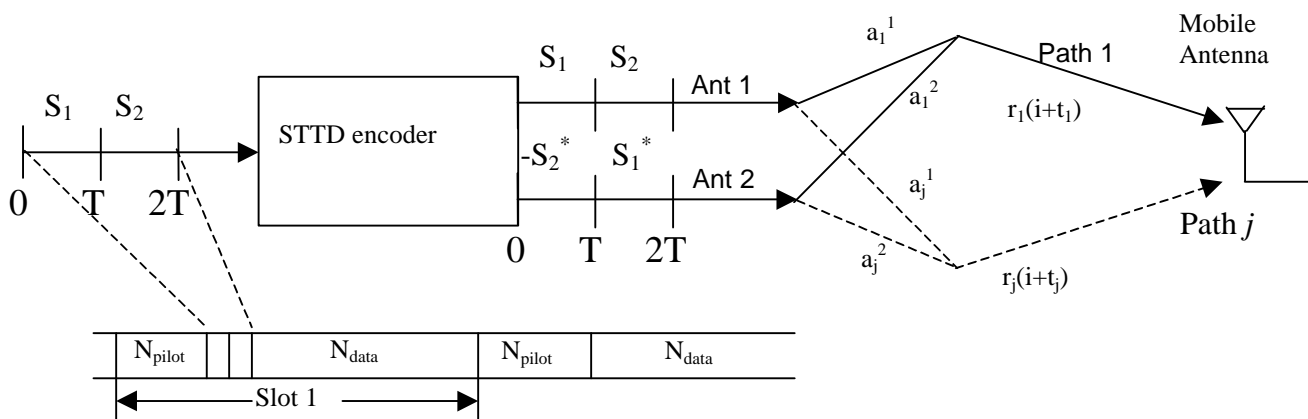

### 5.3.1.2 Open loop transmit diversity

<Editors note: This section has not been updated yet. See Ad Hoc#6.>

The open loop downlink transmit diversity employs a space time block coding based transmit diversity (STTD). A block diagram of the transmitter using STTD for DPCCH and common control channels is shown in the Figure 7 below.

**Figure 9: Block diagram of the transmitter.**

**Figure 10: Block diagram of STTD encoder.**

The  $T$  denotes the symbol time and let the chip time be denoted  $T_c = T/M$ ,  $M$  being the spreading gain. The received signal for the  $j^{\text{th}}$  path of the  $i^{\text{th}}$  chip transmitted between 0 and  $T$  after matched filtering and A/D sampling is given by :

$$r_j(i+t_j) = (a_j^1 S_1 - a_j^2 S_2^*) C(i+t_j) + n_j(i) ; i = 0, \dots, M-1 \quad (1)$$

The  $r_j(i+t_j)$  and  $n_j(i)$  denote (figure 1b) the received signal and the additive AWGN noise,  $t_j$  denotes the propagation delay and  $a_j^i$  denotes the Rayleigh fading coefficients. Similarly, the received signal for transmission time  $[T, 2T)$  is given by :

$$r_j(i+t_j) = (a_j^2 S_1^* + a_j^1 S_2) C(i+t_j) + n_j(i) ; i = M, \dots, 2M-1 \quad (2)$$

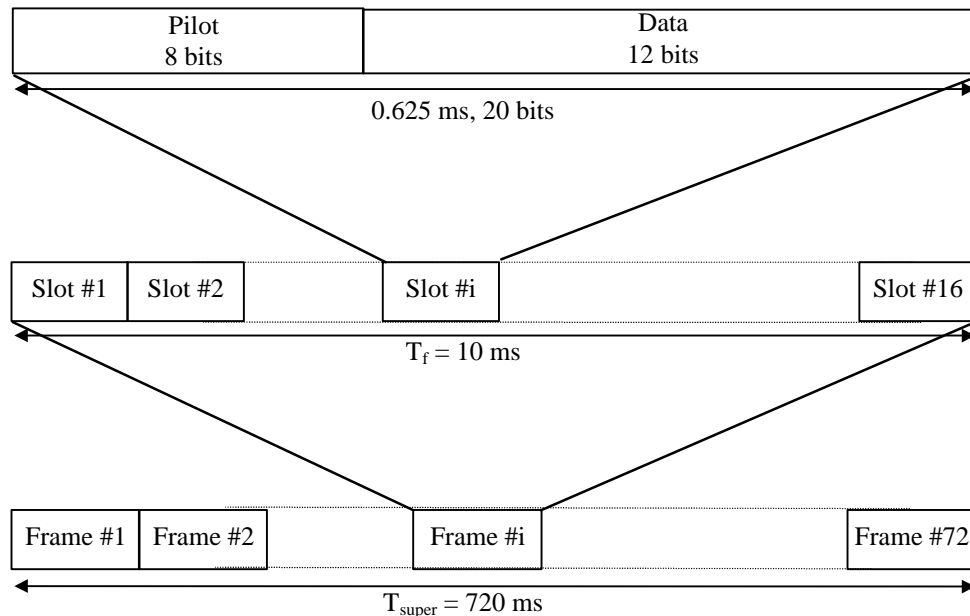

## 5.3.2 Common downlink physical channels

### 5.3.2.1 Primary Common Control Physical Channel (CCPCH)

<Editors note: This section has not been updated yet. see Adhoc #2. ETSI: Primary CCPCH is continuous. ARIB: Primary CCPCH is discontinuous in order to carry time multiplexed SCH.>

<sup>1</sup> Note, FB diversity does set any requirements to the length and position of different fields in the DPCCH slot structure. The slot structure shown in Figure 8 can be considered as an example.

The Primary CCPCH is a fixed rate (32 kbps, SF=256) downlink physical channels used to carry the BCH. Figure 11 shows the frame structure of the Primary CCPCH. The frame structure differs from the downlink DPCH in that no TPC commands or TFCI is transmitted. The only Layer 1 control information is the common pilot bits needed for coherent detection.

**Figure 11: Frame structure for Primary Common Control Physical Channel.**

#### 5.3.2.1.1 Primary CCPCH structure with FB mode transmit diversity

<Editors note: This section has not been updated yet. see Adhoc #6>

If diversity transmission is applied on dedicated forward link channels, the Primary CCPCH pilot is transmitted in parallel from both of the antennas as shown in the Figure 12. Different pilot patterns are applied to the different antennas, indicated in Figure 12 by the difference in shading.

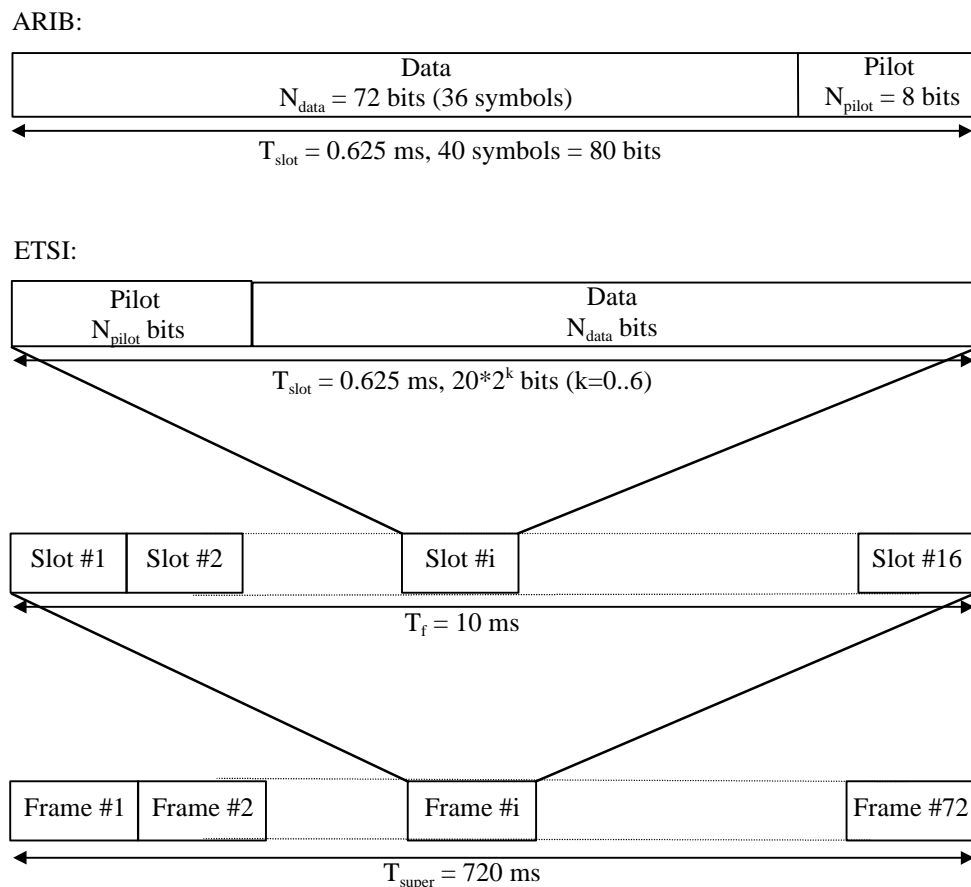

**Figure 12: Slot structure of Primary CCPCH when diversity transmission is applied on dedicated channels.**

Pilot patterns of the antennas are different and (TBD). The transmission powers of the pilot signals on both of the antennas are the same.

#### 5.3.2.2 Secondary Common Control Physical Channel

The secondary CCPCH is used to carry the FACH and PCH. It is of constant rate. However, in contrast to the Primary CCPCH, the rate may be different for different secondary CCPCH within one cell and between cells, in order to be able to allocate different amount of FACH and PCH capacity to a cell. The rate and spreading factor of each secondary CCPCH is broadcast on the BCH. The set of possible rates is the same as for the downlink DPCH, see Section 5.3.1.

The frame structure of the Secondary CCPCH is shown in Figure 13.

**Figure 13: Frame structure for Secondary Common Control Physical Channel.**

The FACH and PCH are mapped to separate Secondary CCPCHs. The main difference between a CCPCH and a downlink dedicated physical channel is that a CCPCH is not power controlled. The main difference between the Primary and Secondary CCPCH is that the Primary CCPCH has a fixed predefined rate while the Secondary CCPCH has a constant rate that may be different for different cells, depending on the capacity needed for FACH and PCH. Furthermore, a Primary CCPCH is continuously transmitted over the entire cell while a Secondary CCPCH is only transmitted when there is data available and may be transmitted in a narrow lobe in the same way as a dedicated physical channel (only valid for a Secondary CCPCH carrying the FACH).

The pilot symbol pattern is described in Table 8. The shadowed part can be used as frame synchronization words. (The symbol pattern of pilot symbols other than the frame synchronization word shall be "11".) In Table 8, the transmission order is from left to right. (Each two-bit pair represents an I/Q pair of QPSK modulation.)

In the Forward Link Common Physical Channel, it is possible to have burst transmission based on radio frame units.

When burst transmission is performed, pilot symbols shall be added to the head of the burst. The number of symbols and the symbol pattern of the pilot symbols to be attached shall take the pattern of Slot #16 in Table 8. The scrambling code phase of the pilot symbol to be added shall have continuous values from the phase of the head of the burst.

<Editors note: Table 8 is defined in ARIB.>

Table 8: Pilot Symbol Pattern

15	11	01	11	00
16	11	00	11	00

### 5.3.2.3 Synchronisation Channel

<Editors note: This section has not been updated yet. see Adhoc #2>

The Synchronisation Channel (SCH) is a downlink signal used for cell search. The SCH consists of two sub channels, the Primary and Secondary SCH. Figure 14 illustrates the structure of the SCH:

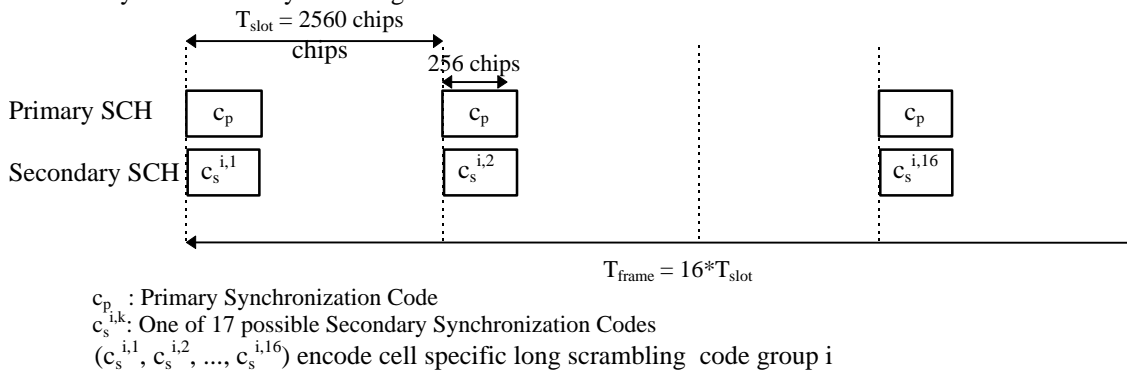

Figure 14: Structure of Synchronisation Channel (SCH).

The Primary SCH consists of an *unmodulated* code of length 256 chips, the Primary Synchronization Code, transmitted once every slot. The Primary Synchronization Code is the same for every cell in the system and is transmitted time-aligned with the BCH slot boundary as illustrated in Figure 14.

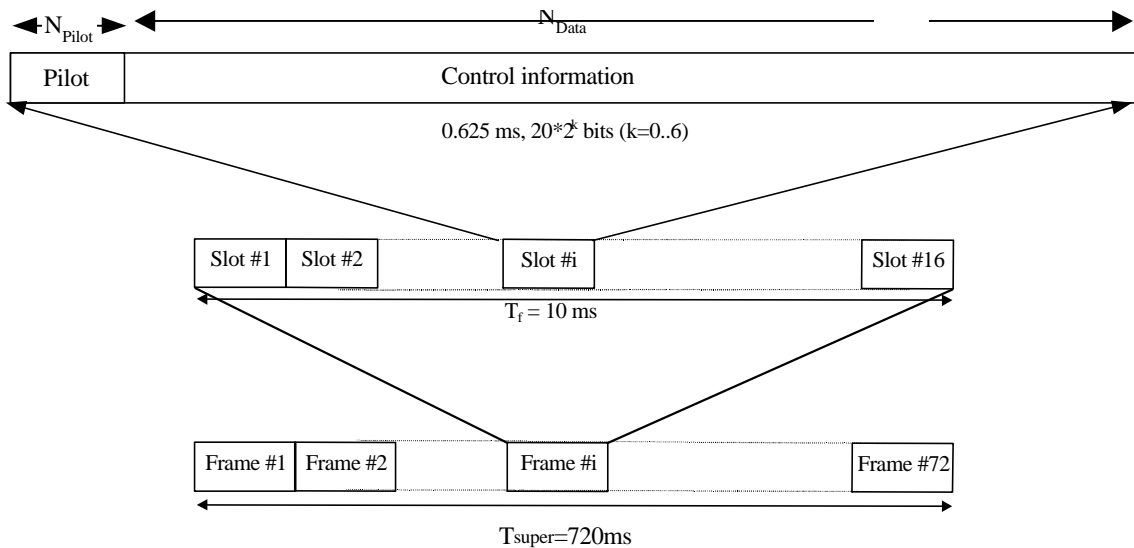

The Secondary SCH consists of repeatedly transmitting a length 16 sequence of *unmodulated* codes of length 256 chips, the Secondary Synchronization Codes, transmitted in parallel with the Primary Synchronization channel. Each Secondary Synchronization code is chosen from a set of 17 different codes of length 256. This sequence on the Secondary SCH indicates which of the 32 different code the cell's downlink scrambling code belongs to. 32 sequences are used to encode the 32 different code groups each containing 16 scrambling codes.

<Editors note: The rest of the original XX.03 section and the the list of sequences (ARIB table 3.2.4-5) have been moved to S1.13.>

### 5.3.2.4 Physical Shared Channel Control Channel (PSCCCH)

<Editors note: ETSI only.>

[The frame structure for the PSCCCH is shown in Figure 15.

**Figure 15: Frame structure of the Physical Shared Channel Control Channel (PSCCCH).**

The PSCCCH contains pilot symbols, and a control information field. The control information field can include TPC commands concerning several users. Other control information includes code assignment for the DSCH, but could also comprise other type of information if needed. The TPC commands would come in support of fast closed loop power control of the PDSCH, and thus, would have to be decoded on a slot-by-slot basis. The exact structure of the control information field is for further study.

### 5.3.2.5 Physical Downlink Shared Channel

<Editors note: ETSI only.>

The Physical Downlink Shared Channel (PDSCH), used to carry the Downlink Shared Channel (DSCH), is shared by users based on code multiplexing. It is always associated with another physical channel, as follows:

- If the DSCH is associated with a DCH, the PDSCH is associated with a DPCH,
- If the DSCH is associated with a DSCH control channel, the PDSCH is associated with a PSCCCH.

This is described respectively in sections 5.3.2.5.1 and 5.3.2.5.2.

In both cases, the PDSCH does not comprise any pilot symbols, since this does not seem to be required at this stage, given information provided on the associated DPCH or PSCCCH. This still needs to be verified.

#### 5.3.2.5.1 DSCH associated with a DCH

The frame structure of the DSCH, when associated with a DCH, is shown on Figure 16.

**Figure 16: Frame structure for the DSCH when associated to a DCH.**

To indicate for UE that there is data to decode on the DSCH, two signalling methods are possible, either using the TFCI field, or higher layer signalling.

#### 5.3.2.5.2 DSCH associated with a DSCH control channel

The frame structure of the DSCH when associated with a DSCH control channel is shown on Figure 17.

Figure 17: Frame structure for the DSCH when associated to a DSCH control channel.

### 5.3.2.6 Acquisition Indication Channel (AICH)

<Editors note: related to PRACH, see Adhoc #3.>

The acquisition indication channel (AICH) carries the acquisition indicators. The acquisition indicator  $AI_i$  corresponding to signature  $i$  is transmitted on the downlink, as a response to the detection of signature  $i$  on a PRACH.  $AI_i$  is signature  $i$  (16 symbols, see UMTS XX.05) spread by a channelization code of length 256.]

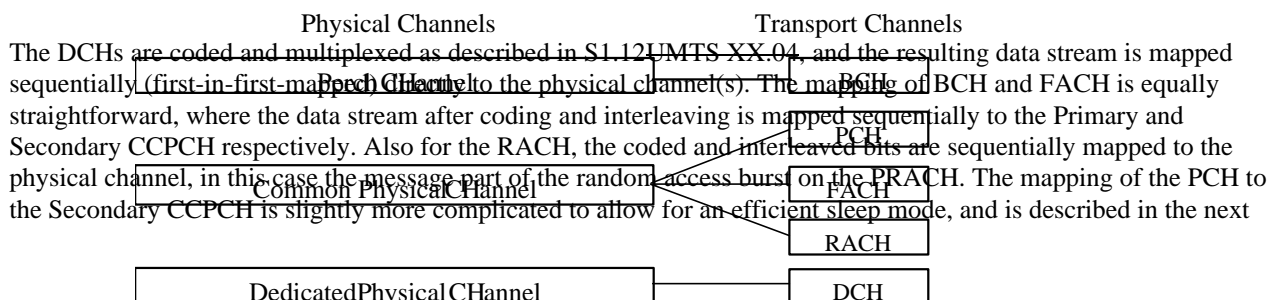

## 6 Mapping of transport channels to physical channels

Figure 18 summarises the mapping of transport channels to physical channels.

Transport Channels	Physical Channels
BCH	Primary Common Control Physical Channel (Primary CCPCH)
FACH	Secondary Common Control Physical Channel (Secondary CCPCH)
PCH	
RACH	Physical Random Access Channel (PRACH)
FAUSCH	
DCH	Dedicated Physical Data Channel (DPDCH) Dedicated Physical Control Channel (DPCCH) Synchronisation Channel (SCH)
DSCH	Physical Downlink Shared Channel (PDSCH)
DSCH control channel	Physical Shared Channel Control Channel (PSCCCH) Acquisition Indication Channel (AICH)

Figure 18: Transport-channel to physical-channel mapping.

<Editors note: ARIB mapping:>

The DCHs are coded and multiplexed as described in S1.12 UMTS XX.04, and the resulting data stream is mapped sequentially (first-in-first-mapped) to the physical channel(s). The mapping of BCH and FACH is equally straightforward, where the data stream after coding and interleaving is mapped sequentially to the Primary and Secondary CCPCH respectively. Also for the RACH, the coded and interleaved bits are sequentially mapped to the physical channel, in this case the message part of the random access burst on the PRACH. The mapping of the PCH to the Secondary CCPCH is slightly more complicated to allow for an efficient sleep mode, and is described in the next

section. The mapping of the DSCH to the PDSCH is done by mapping the data stream sequentially (first-in-first-mapped) directly to the physical channel.

## 6.1 Method for mapping of PCH to Secondary CCPCH

*<Editors note: sliding paging configuration FFS in ARIB. Basic PCH mapping is identical.>*

The method used to map the paging blocks to the Secondary CCPCH is shown in Figure 19.

The PCH is divided into several blocks in one superframe. Paging groups are mapped to the paging blocks where layer 3 information to each group is transmitted.

The mapping between a paging group "i" and the paging block f(i), which is numbered between 1 and 288, is according

$$f(i)=i \quad (\text{fixed mapping ARIB})$$

$$f(i)=((i+\text{SUFN}) \bmod N_{\text{PB}}) + 1 \quad (\text{sliding paging mapping to improve sleep mode, ETSI})$$

where SUFN is the superframe number and  $N_{\text{PB}}=288$  paging blocks per superframe. Thereby a paging group is mapped to the paging blocks

$$(i, i, \dots) \quad (\text{ARIB})$$

$$(i, i+1, i+2, \dots, 288, 1, 2, \dots) \quad (\text{ETSI})$$

when the superframe number increases.

Each block on the PCH carries information amount worth of 4 slots, and consists of a total of 6 information parts: 2

Paging Indication (PI) parts - for indicating whether there are paging messages or not, and 4 Mobile User Identifier (MUI) parts - for indicating the identity of the UE and carrying the actual paging message.

In each block, PI parts are transmitted ahead of MUI parts.

In all groups, 6 information parts are allocated with a certain pattern in the range of 24 slots. By shifting each pattern by 4 slots, multiple 288 blocks of PCH can be allocated on one Secondary Common Control Physical Channel.

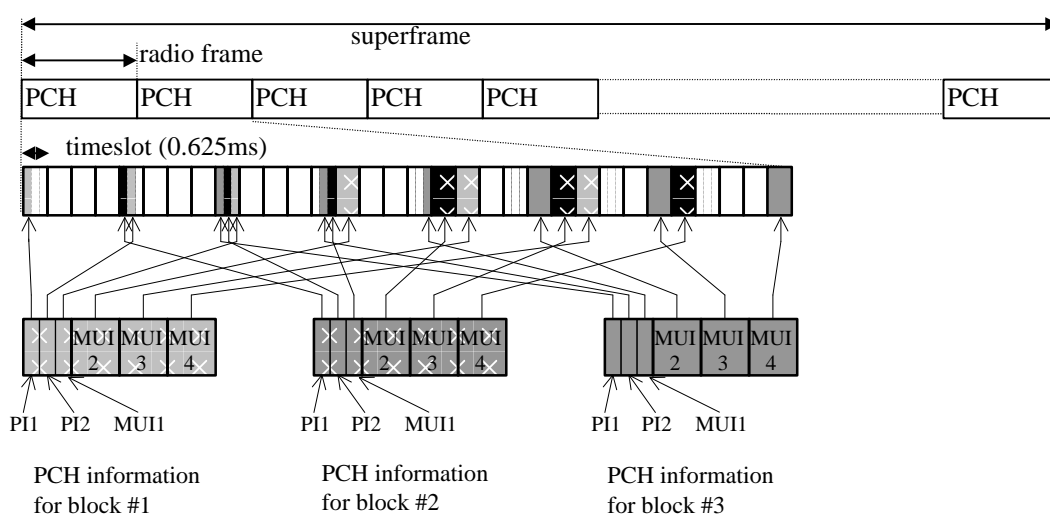

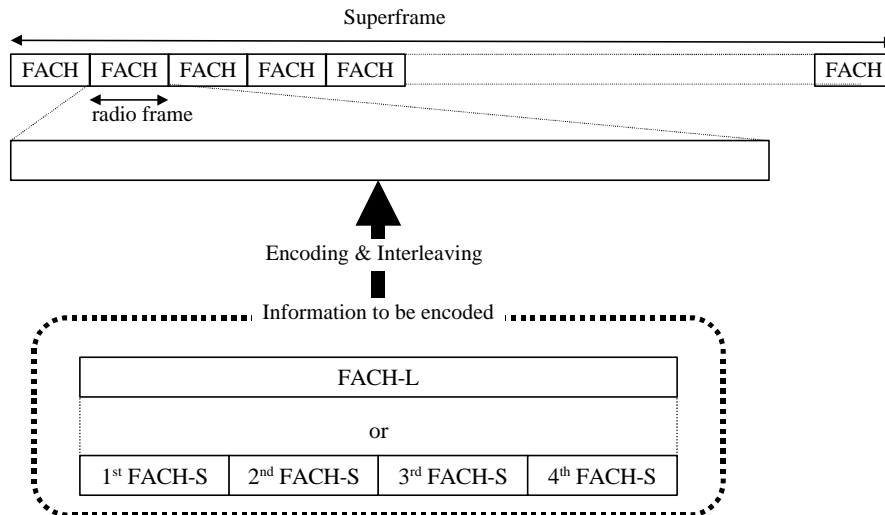

Figure 19: PCH mapping method.

## 6.2 Method for mapping of FACH to Secondary CCPCH

*<Editors note: ARIB only>*

[Fig. XX-2 shows mapping method of FACH. There are two transport formats, FACH-S and FACH-L for FACH transmission. Which transport format to use is determined by MAC sub-layer depending on the amount of information to be transmitted on FACH.]

*Fig.XX-2 FACH Mapping Method]*

## 7 Timing relationship between physical channels

<Editors note: The parameter  $M$  is not defined in ETSI. In ARIB it is  $M=36864=512*72$ . Bit allocation for SFN and example SFN transmission are given in ARIB Vol.3 section 3.2.2.2.3.>

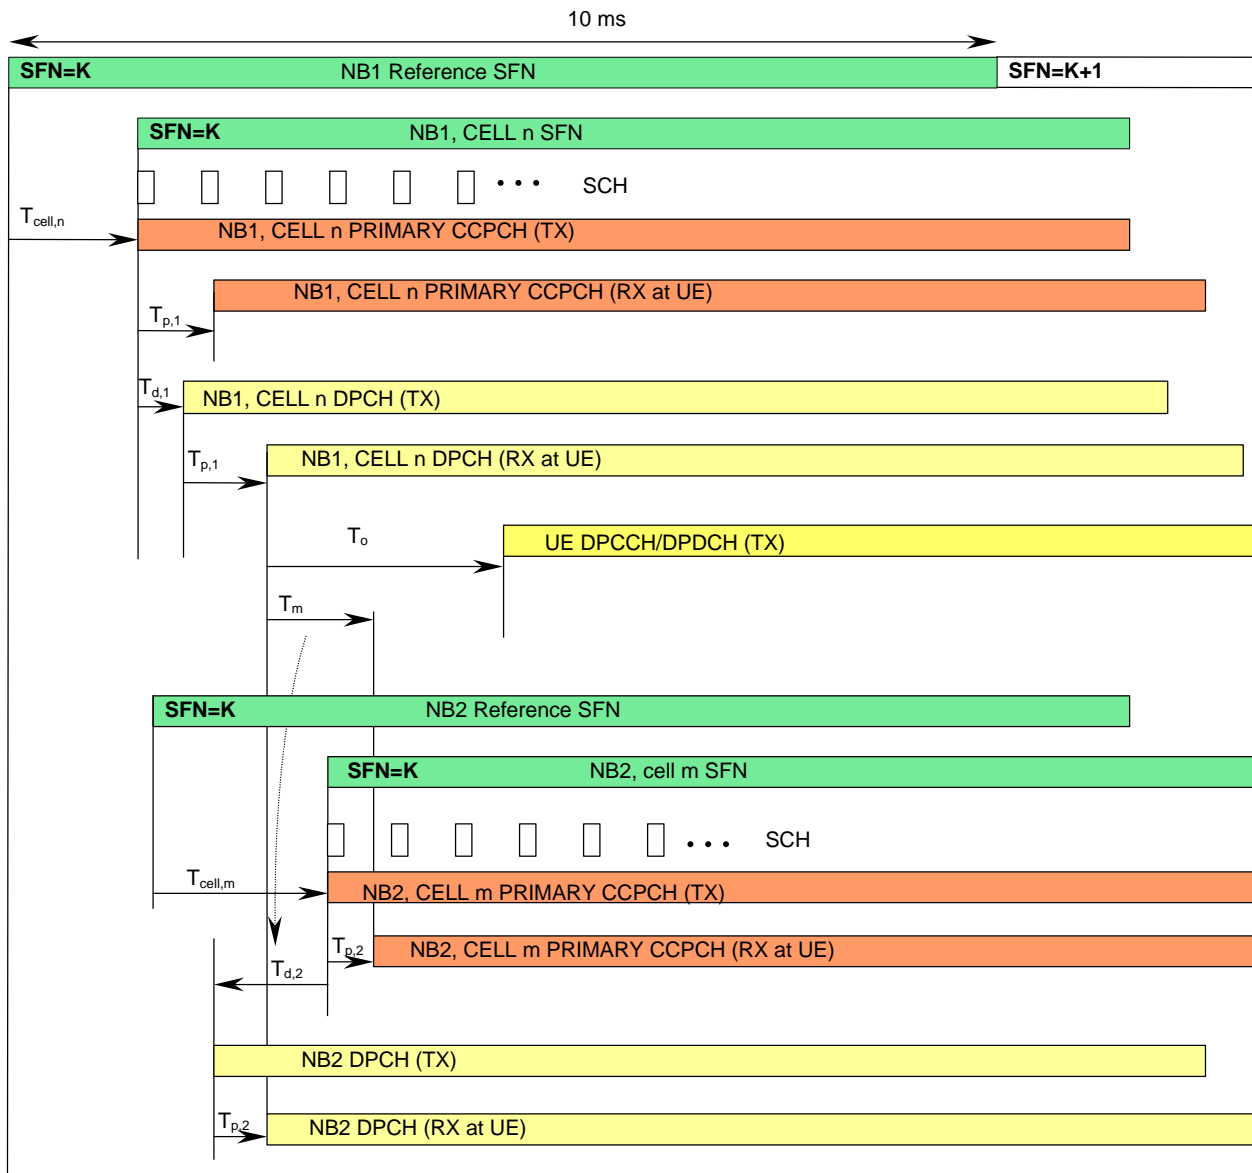

In general, a Node B covers  $N$  cells, where  $N \ll 1$ . Each Node B has a Reference System Frame Number (SFN), which counts from 0 to  $M-1$  in Radio Frame (10 ms) intervals.  $M$  is a multiple of the superframe (72), and is TBD. The purpose of the Reference SFN is to make sure that the correct frames are combined at soft handover. Each cell has a Cell SFN, which is broadcast on the BCH. [Figure XX-3 shows how the SFN is transmitted on the BCH.]

*Fig. XX-3 Example of SFN transmission*

Figure 20 shows the proposed physical channel timing parameters in a soft handover situation including two Node Bs, NB1 and NB2. The timing parameters in Figure 20 refer to frame-timing.

**Figure 20: Physical channel timing relations.**

The parameters in Figure 20 are explained below:

- $T_p$ : Propagation delay between Node B and UE.
- $T_{cell}$ : This timing offset is used for the frame timing of SCH, Primary CCPCH and the starting phase of all downlink scrambling codes in a cell. The main purpose is to avoid having overlapping SCHs in different cells belonging to the same Node B. The resolution, which affects the number of possible cells in a Node B, is TBD and depends on the maximum expected time-dispersion. The range is one slot.  $T_{cell}$  is also the reference frame timing for the PRACH.
- $T_d$ : This timing offset is used for the frame timing of DPCHs and Secondary CCPCHs. It can be individually set up for each DPCH and Secondary CCPCH. The  $T_d$  values for the latter may be broadcast on the BCH, or known a-priori. The purpose of  $T_d$  is:
  - In an originating/terminating cell, to distribute discontinuous transmission periods in time, and also to distribute Node B-RNC transmission traffic in time.
  - At soft handover, to synchronise downlink DPCHs to the same UE, in order to minimise the buffering requirements at the UE.
 The resolution is 256 chips in order to maintain downlink orthogonality and the range is TBD.
- $T_o$ : This constant timing offset is used to set up the transmission frame timing of an uplink DPCCH/DPDCH in the UE. The uplink DPCCH/DPDCH transmission frame timing should be set to  $T_o$  seconds after the frame timing of the earliest received path of the downlink DPCH.  $T_o$  should be chosen to minimise the closed loop PC delay in as large cell-radii as possible. The value is TBD. The starting phase of the uplink scrambling code is synchronised with the uplink DPCCH/DPDCH frame timing.

- $T_m$ : This value is measured by the UE and reported to the RNC prior to soft handover. The RNC can then notify this value to the target cell, which then knows how to set  $T_d$  to achieve proper reception and transmission frame timing of the dedicated physical channel.

Note that since the UE reports the value  $T_m$  as the time-difference between the received Primary CCPCH frame-timing from the target cell and the earliest received existing DPCH path, the propagation delay to the target cell is already compensated for in the setting of  $T_d$  at the target cell. The DPCH signal from the target cell will reach the UE at the same time as the earliest received existing DPCH path. The only remaining error, besides frequency-drift and UE mobility related errors, is due to a (known) rounding error at the target cell in order to maintain downlink orthogonality.

<Editors note: The timing in AIB is described in section 3.2.5 of Vol.3. The timing parameters in ARIB are very similar, the correspondance between the parameters is as follows:

$T_p$ : propagation delay

$T_{cell}$ :  $T_{SECT}$

$T_d$ :  $T_{CPCH\_OF} (T_{FRAME} + T_{SLOT})$  depending on channel type

$T_0$ : 1024 chips

$T_0 - T_m$ :  $T_{DHO}$

The scrambling code phase is aligned to the primary CCPCH. The ARIB parameter  $T_{OFFSET}$  can be used as an offset value of the scrambling code phase of DL dedicated physical channel in order to prevent code shortage. This should be discussed in Adhoc#10.

The timing of the RACH is described in detail in section 5.2.2.1.>

<Editors note: The Power control timing described in this section should be seen as an example on how the control bits have to be placed in order to permit a short TPC delay. It seems appropriate to move this part later.>

### **Power control timing**

In order to maximize the BTS-MS distance within which one-slot control delay is achieved, the frame timing of a reverse link DPCH is delayed by 250 $\mu$ s from that of the corresponding forward link DPCH measured at the MS antenna. Responding to a forward link TPC command, MS shall change its reverse link DPCH output power at the beginning of the first reverse link pilot field after the TPC command reception. Responding to a reverse link TPC command, BTS shall change its DPCH output power at the beginning of the first of later forward link pilot field after the TPC command reception. Note that the delay from the reverse link TPC command reception to the power change timing is not specified for BTS. MS shall decide and send TPC commands on the reverse link based on the forward link SIR measurement. The TPC command field on the reverse link starts, when measured at the MS antenna, 125 $\mu$ s after the end of forward link pilot field. BTS shall decide and send TPC commands based on the reverse link SIR measurement. However, the SIR measurement periods are not specified either for MS or BTS.

Fig. XX-4 illustrates an example of transmitter power control timings.
