Reason for change:	⌘	As there is no cryptographic key separation between GSM / GPRS encryption algorithms, it cannot be controlled with which algorithm the ciphering key may be used.
Summary of change: ⌘		Introduces the special RAND mechanism described in [S3-030588] to restrict the ciphering algorithms with which a particular GSM or GPRS ciphering key may be used
Consequences if not approved:	⌘	There is no mean to restrict the algorithms with which the ciphering key may be used.

***** BEGIN SET OF CHANGES *****

3 Subscriber identity authentication

3.1 Generality

The definition and operational requirements of subscriber identity authentication are given in GSM 02.09.

The authentication procedure will also be used to set the ciphering key (see clause 4). Therefore, it is performed after the subscriber identity (TMSI/IMSI) is known by the network and before the channel is encrypted.

Two network functions are necessary: the authentication procedure itself, and the key management inside the fixed subsystem.

3.2 The authentication procedure

The authentication procedure consists of the following exchange between the fixed subsystem and the MS.

- The fixed subsystem transmits a ~~non-predictable number~~128-bit A3 and A8 input parameter RAND to the MS. The exact structure of RAND is specified in Annex C. RAND contains a non-predictable number, and also allows an Encryption Algorithms Restriction Vector ~~-~~ (EARV) to be derived that describes~~ing~~ restrictions on the set of encryption algorithms the MS is authorized to use with the ciphering key~~Encryption~~ (see Annex C, Section C.4).

- The MS computes the signature of RAND, say SRES, using algorithm A3 and some secret information: the Individual Subscriber Authentication Key, denoted below by Ki.

- The MS transmits the signature SRES to the fixed subsystem.

- The fixed subsystem tests SRES for validity.

The general procedure is schematized in figure 3.1.
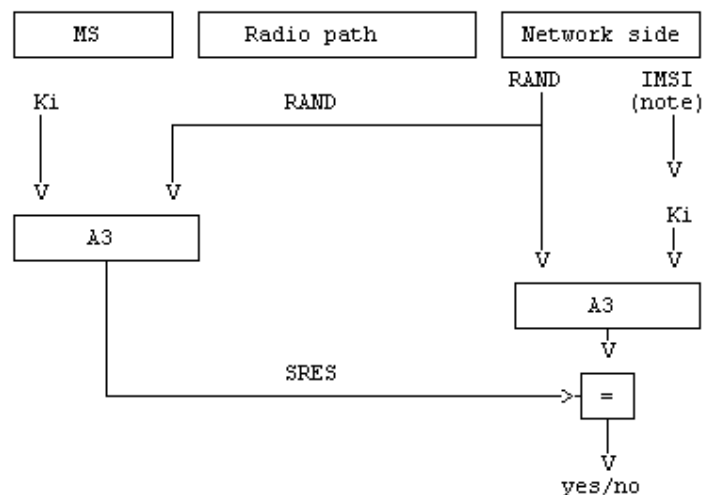

NOTE: IMSI is used to retrieve Ki in the network.

Figure 3.1: The authentication procedure

Authentication algorithm A3 is specified in annex C.

***** END SET OF CHANGES *****

***** BEGIN SET OF CHANGES *****

4.3 Key setting

Mutual key setting is the procedure that allows the mobile station and the network to agree on the key Kc to use in the ciphering and deciphering algorithms A5.

A key setting is triggered by the authentication procedure. Key setting may be initiated by the network as often as the network operator wishes.

Key setting must occur on a DCCH not yet encrypted and as soon as the identity of the mobile subscriber (i.e. TMSI or IMSI) is known by the network.

The transmission of Kc to the MS is indirect and uses the authentication RAND value; Kc is derived from RAND by using algorithm A8 and the Subscriber Authentication key Ki, as defined in annex C.

As a consequence, the procedures for the management of Kc are the authentication procedures described in subclause 3.3.

The values Kc are computed together with the SRES values. The security related information (see subclause 3.3.1) consists of RAND, SRES and Kc.

The key Kc and the encryption algorithms restriction vector (EARV) derived from RAND is are stored by the mobile station until it is updated at the next authentication.

If for any reason the encryption algorithms restriction vector (EARV) associated with Kc is lost, the MS behaves as if no Kc value is available in the mobile when a "start cipher" message is received from the network without prior Kc update and when the CKSN value associated with Kc has to be sent to the network.

Key setting is schematized in figure 4.1.

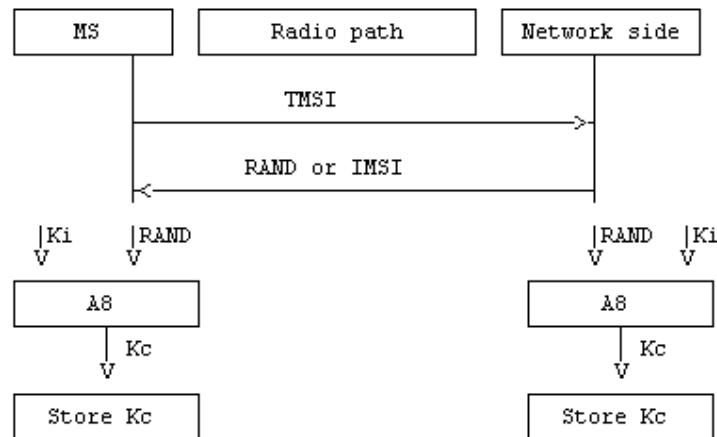

Figure 4.1: Key setting

4.4 Ciphering key sequence number

The ciphering key sequence number is a number which is associated with the ciphering key Kc and they are stored together in the mobile station and in the network.

However since it is not directly involved in any security mechanism, it is not addressed in this specification but in GSM 04.08 instead.

4.5 Starting of the ciphering and deciphering processes

The MS and the BSS must co-ordinate the instants at which the enciphering and deciphering processes start on DCCH and TCH.

On DCCH, this procedure takes place under the control of the network some time after the completion of the authentication procedure (if any), or after the key Kc has been made available at the BSS.

No information elements for which protection is needed must be sent before the ciphering and deciphering processes are operating.

The transition from clear text mode to ciphered mode proceeds as follows: deciphering starts in the BSS, which sends in clear text to the MS a specific message, here called "Start cipher". The MS checks that the requested encryption algorithm is authorized by the Encryption Algorithms Restriction Vector (EARV) associated with Kc. Both the enciphering and deciphering start on the MS side after the message "Start cipher" has been correctly received by the MS. Finally, enciphering on the BSS side starts as soon as a frame or a message from the MS has been correctly deciphered at the BSS.

The starting of enciphering and deciphering processes is schematized in figure 4.2.

A.3   List of abbreviations

In addition to the abbreviations listed in GSM 01.04, the following abbreviations are used in the schemes:

A3	authentication algorithm
A5	signalling data and user data encryption algorithm
A8	ciphering key generating algorithm
BSS	Base Station System
EARV	Encryption Algorithms Restriction Vector
HLR	Home Location Register
IMSI	International Mobile Subscriber Identity
Kc	ciphering key
Kc[M]	message encrypted with ciphering key Kc
Kc[TMSI]	TMSI encrypted with ciphering key Kc
Ki	individual subscriber authentication key
LAI	Location Area Identity
MS	Mobile Station
MSC	Mobile services Switching Centre
R	Random number (RAND)
S	Signed response (SRES)
TMSI o/n	Temporary Mobile Subscriber Identity old/new
VLR o/n	Visitor Location Register old/new

***** END SET OF CHANGES *****

***** BEGIN SET OF CHANGES *****

B.2.4   Mobile Station (MS)

The mobile station stores permanently:

- authentication algorithm A3;

- encryption algorithm A5;

- ciphering key generating algorithm A8;

- individual subscriber authentication key Ki;

- ciphering key Kc;

- encryption algorithms restriction vector

- ciphering key sequence number;

- TMSI.

The mobile station generates and stores:

- ciphering key Kc.

The mobile station receives and stores:

- ciphering key sequence number;

- TMSI;

- LAI.

***** BEGIN SET OF CHANGES *****

C.3 Algorithm A8

Algorithm A8 is considered as a matter for GSM PLMN operators as is Algorithm A3.

A proposal for a possible Algorithm A8 is managed by GSM/MoU and available upon appropriate request.

C.3.1 Purpose

As defined in GSM 03.20, Algorithm A8 must compute the ciphering key Kc from the random challenge RAND sent during the authentication procedure, using the authentication key Ki.

C.3.2 Implementation and operational requirements

On the MS side, Algorithm A8 is contained in the SIM, as specified in GSM 02.17.

On the network side, Algorithm A8 is co-located with Algorithm A3.

The two input parameters (RAND and Ki) and the output parameter (Kc) of Algorithm A8 shall follow the following formats:

- length of Ki: 128 bits;

- length of RAND: 128 bits;

- length of Kc: 64 bits.

Since the maximum length of the actual ciphering key is fixed by GSM/MoU, Algorithm A8 shall produce this actual ciphering key and extend it (if necessary) into a 64 bit word where the non-significant bits are forced to zero. It is assumed that any non-significant bits are the least significant bits and that, the actual ciphering key is contained in the most significant bits. For signalling and testing purposes the ciphering key Kc has to considered to be 64 unstructured bits.
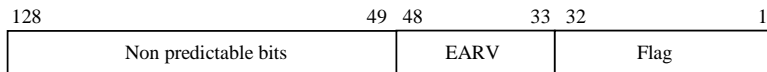

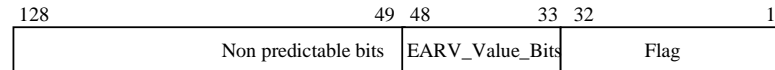

C.4 Structure of RAND

This Section describes how the MS shall interpret the 128-bit values RAND it receives from the network at authentication. The received 128-bit RAND value may be either a special RAND value, whichthe structure of which is depicted in the scheme hereafter, or simply be an unstructured value consisting of 128 non predictable bits. It is left as an home operator option to use either structure. In both cases, the received RAND value is taken (unmodified) as the input to the authentication and ciphering key generation algorithms A3 and A8, and also allows the MS to derive the Encryption Algorithms Restriction Vector (EARV) associated with the ciphering key derived from RAND.

The EARV derivation procedure in the MS is the following: The MS checks whether bits 1 to 32 of RAND (contained in the 4 first octets of RAND) are all set to 1. If this is the case, the received RAND is treated as a special RAND value, and the EARV value is extracted from bits 33-48 of RAND as explained below. Otherwise, the received RAND value is interpreted as an unstructured value: bits 33-48 have no specific signification, and the 16 EARV bits to be stored in the MS are set to 1.

The EARV value consists of 16 binary values indicating which of the algorithms A5/0 to A5/7 and GEA0 to GEA7 are authorised (namely which associated binary value is equal to 1). The EARVvalue derived from RAND is stored in the MS at the same time as the associated ciphering key. Each time a command governing the encryption state of the MS is received from the network (e.g. CIPHER MODE COMMAND in circuit-switched GSM, AUTHENTICATION AND ENCRYPTION REQUEST in GPRS, etc.), the consistency of the requested algorithm with the EARV value associated with the current ciphering key value (Kc or GPRS-Kc) shall be checked by the MS, and the command shall not be executed if the binary value corresponding to the requested algorithm is set to 0. The binary value associated with A5/0 (circuit switched GSM) or GEA0 (GPRS) shall be checked every time a command instructing the MS not to cipher is

received from the network, and the command shall not be executed if the binary value associated with A5/0 (resp. GEA0) is set to 0.

~~RAND is a 128-bit value with the following structure.~~ The structure of special RAND values is the following:

Non predictable bits	EARV_Value_Bits	Flag

128   49 48   33 32   1

Non predictable bits	EARV	Flag

128   49 48   33 32   1

Bit 1 corresponds to bit 1 of byte 1 of RAND and bit 128 corresponds to the bit 8 of byte 16 of RAND.

- length of Flag: 32 bits;

- length of ~~Encryption Algorithms Restriction Vector (~~EARV_Value_Bits ~~)~~:   16 bits;

- length of Non predictable bits: 80 bits.

Flag :

In special RAND values, ~~If the~~the flag is set to a particular ~~value~~binary pattern (all 32 bits set to 1) to indicated that ~~.~~ bits 33-48 shall be interpreted by the MS as the EARV value~~as defined below otherwise bits 33-48 have no specific signification.~~

EARV_Value_Bits~~:~~:

In special RAND values, the EARV_Value_Bits parameter ~~I~~indicates which encryption algorithms the ciphering key value K_C or GPRS-K~~C~~c derived from RAND may be used with. Bits 33-40 indicate which of A5/0…A5/7 it may be used with, and bits 41–48 indicate which of GEA0…GEA7 it may be used with. For each of these 16 bits, value 1 indicates that the corresponding algorithm is allowed and value 0 indicates that the corresponding algorithm is forbidden.

***** END SET OF CHANGES *****

***** BEGIN SET OF CHANGES *****

D.3 Subscriber identity authentication

D.3.1 Generality

The definition and operational requirements of subscriber identity authentication are given in GSM 02.09.

The authentication procedure may be performed at any time by the network.

The authentication procedure will also be used to set the ciphering key (see clause D.4). Therefore, it is performed after the subscriber identity (TLLI/IMSI) is known by the network for the management of new ciphering.

Two network functions are necessary: the authentication procedure itself, and the key management.

D.3.2 The authentication procedure

The authentication procedure is described in subclause 3.2.

D.3.3 Subscriber Authentication Key management

The management of Subscriber Authentication Key (Ki) is described in subclause 3.3.

D.3.3.1 General authentication procedure

When needed, the SGSN requests security related information for a MS from the HLR/AuC corresponding to the IMSI of the MS. This includes an array of pairs of corresponding RAND and SRES. These pairs are obtained by applying Algorithm A3 to each RAND and the key Ki as shown in figure 3.1. The pairs are stored in the SGSN as part of the security related information.

The procedure used for updating the vectors RAND/SRES is schematised in figure D.3.2.

NOTE: The Authentication Vector Response contains also GPRS-Kc(1..n) which is not shown in this and the following figures. For discussion of GPRS-Kc see clause D.4.

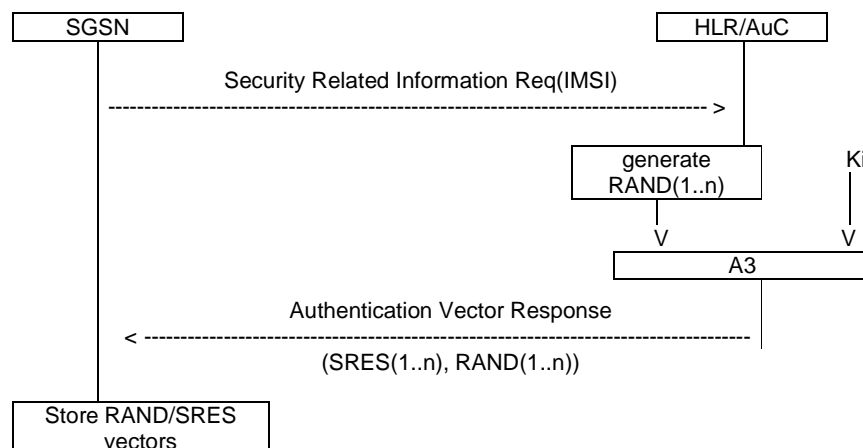

Figure D.3.2: Procedure for updating the vectors RAND/SRES

When an SGSN performs an authentication, including the case of a routing area updating within the same SGSN area, it chooses a 128-bit RAND value in the array corresponding to the MS. The exact structure of RAND is specified in Annex C. RAND contains a non-predictable number, and also allows an Encryption Algorithms

Restriction Vector (EARV) to be derived that describesing restrictions on the set of encryption algorithms the MS is authorized to use with the ciphering keyEncryption (see Annex C, Section C.4).

It then tests the answer from the MS by comparing it with the corresponding SRES, as schematised in figure D.3.3.

Figure D.3.3: General authentication procedure

***** END SET OF CHANGES *****

***** BEGIN SET OF CHANGES *****

D.4.3   Key setting

Mutual key setting is the procedure that allows the mobile station and the network to agree on the key GPRS-Kc to use in the ciphering and deciphering algorithms GPRS-A5. This procedure corresponds to the procedure described in subclause 4.3 besides the different confidential subscriber identity. The GPRS-Kc is handled by the SGSN independently from the MSC. If a MS is using both circuit switched and packet switched, two different ciphering keys will be used independently, one (Kc) in the MSC and one (GPRS-Kc) in the SGSN.

A key setting is triggered by the authentication procedure. Key setting may be initiated by the network as often as the network operator wishes. If an authentication procedure is performed during a data transfer, the new ciphering parameters shall be taken in use immediately at the end of the authentication procedure in both SGSN and MS.

Key setting may not be encrypted and shall be performed as soon as the identity of the mobile subscriber (i.e. TLLI or IMSI) is known by the network.

The transmission of GPRS-Kc to the MS is indirect and uses the authentication RAND value; GPRS-Kc is derived from RAND by using algorithm A8 and the Subscriber Authentication key Ki, in the same way as defined in annex C for Kc.

As a consequence, the procedures for the management of GPRS-Kc are the authentication procedures described in subclause D.3.3.

The values GPRS-Kc are computed together with the SRES values. The security related information (see subclause D.3.3.1) consists of RAND, SRES and GPRS-Kc.

The key GPRS-Kc and the encryption algorithms restriction vector (EARV) derived from RAND are is stored by the mobile station until it is updated at the next authentication.

If for any reason- the encryption algorithms restriction vector (EARV) associated with GPRS-Kc is lost, the MS behaves as if no Kc value is available in the mobile when an authentication and ciphering request is received from the network without prior GPRS-Kc update and when- the GPRS-CKSN value associated with GPRS-Kc has to be sent to the network.
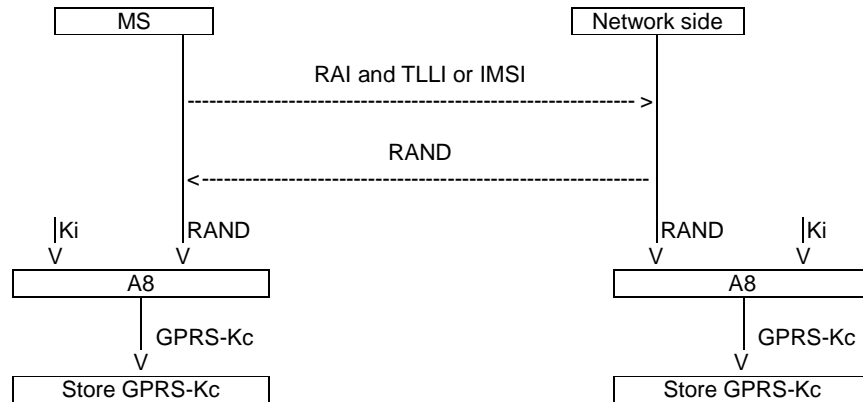

Key setting is schematised in figure D.4.1.

Figure D.4.1: Key setting

D.4.4   Ciphering key sequence number

The GPRS-CKSN (Ciphering Key Sequence Number) is a number which is associated with each ciphering key GPRS-Kc. The GPRS-CKSN and GPRS-Kc are stored together in the mobile station and in the network. It permits the consistency check of the keys stored in the MS and in the network. Two independent pairs, Kc and CKSN (for circuit switched), and GPRS-Kc and GPRS-CKSN (for packet switched) may be stored in the MS simultaneously.

However since it is not directly involved in any security mechanism, it is not addressed in this specification but in GSM 04.08 instead.

D.4.5   Starting of the ciphering and deciphering processes

The MS and the SGSN must co-ordinate the instants at which the ciphering and deciphering processes start. The authentication procedure governs the start of ciphering. The SGSN indicates if ciphering shall be used or not in the Authentication and Ciphering Request message. If ciphering is used, the MS starts ciphering after checking that the requested encryption algorithm is authorized by the Encryption Algorithms Restriction Vector- (EARV) associated with GPRS-Kc.and sending the Authentication and Ciphering Response message. The SGSN starts ciphering when a valid Authentication and Ciphering Response message is received from the MS.

Upon GPRS Attach, if ciphering is to be used, an Authentication and Ciphering Request message shall be sent to the MS to start ciphering.

If the GPRS-CKSN stored in the network does not match the GPRS-CKSN received from the MS in the Attach Request message, then the network should authenticate the MS.

As an option, the network may decide to continue ciphering without authentication after receiving a Routing Area Update Request message with a valid GPRS-CKSN. Both the MS and the network shall use the latest ciphering parameters. The MS starts ciphering after a receiving a valid ciphered Routing Area Update Accept message from the network. The SGSN starts ciphering when sending the ciphered Routing Area Update Accept message to the MS.

Upon delivery of the Authentication and Ciphering Response message or the Routing Area Update Accept message, the GPRS Mobility and Management entity in both SGSN and MS shall be aware if ciphering has started or not. LLC provides the capability to send both ciphered and unciphered PDUs. The synchronisation of ciphering at LLC frames level is done by a bit in the LLC header indicating if the frame is ciphered or not. Only a few identified signalling messages (e.g., Routing Area Update Request message) described in GSM 04.08 may be sent unciphered, any other frames sent unciphered shall be deleted. Once the encryption has been started, neither the MS nor the network shall go to an unciphered session.

***** END SET OF CHANGES *****
